Results from Study 1 indicate that different orientations toward developing or demonstrating social competence can be seen in young adolescents' descriptions of their social goals and evaluations of social competence. The majority of students had comments that could be coded as evidence of a social development or social demonstration goal orientation. Different questions yielded different percentages of development versus demonstration goals, but evidence of both was found in each question; looking at responses across the questions, there was clear evidence for both types of social achievement goals. The fact that different orientations to social competence could be seen when students wrote a sentence or two is convincing that this is relevant and potentially important. Study 1 also documented both approach and avoidance goals in students' social strivings. It is interesting that there was a higher percentage of approach than avoid goals, and this was particularly true for the development goals. This is consistent with theories that mastery-avoid goals are less prevalent (Elliot, 2005). This result supports our decision not to include a development-avoid goal in this initial investigation of social achievement goals for young adolescents, but given that there were examples of development-avoid goals, it may be important for future research to attend to them. Overall, Study 1 established that an achievement goal framework is relevant to young adolescents' social motivation.

### Study 2

In Study 2, informed by Study 1, we created new survey items to assess individual differences in young adolescents' social achievement goals. Study 2 was guided by several key aims. First, we examined whether the three social achievement goals (development, demonstration-approach, demonstration-avoid) are distinct and reliable constructs. Given the new nature of the measure, we used exploratory factor analysis. Second, we examined the correlations among the social achievement goals to better understand the nature of social achievement goals in young adolescents. We expected a moderate correlation between goals that shared a focus on demonstration (i.e., demonstration-approach and demonstration-avoid goals; Horst et al., 2007; Ryan & Shim, 2006). Third, we examined the correlations between perceived social competence and social achievement goals. We expected perceived social competence to be positively related to both approach goals (development and demonstration-approach goals) and negatively related to demonstration-avoid goals (Ryan & Shim, 2006).

Next, we examined the relation of social achievement goals to social adjustment. Consistent with our conceptualization that goals precede social adjustment, we used a prospective longitudinal design to examine whether social achievement goals foreshadow subsequent social adjustment (3-month time span). We expected that different social achievement goals would set in motion different ways of engaging in the social world and have different

implications for social adjustment. In line with the focus on developing social skills and relationships, a social development goal would be positively associated with subsequent prosocial behavior and negatively associated with subsequent aggressive behavior. In line with the focus on demonstrating social desirability relative to others, a social demonstration-approach goal would be positively associated with both prosocial and aggressive behavior. In line with the focus on avoiding negative judgments from others, a social demonstration-avoid goal would be positively associated with subsequent anxious solitary behavior and social worry. Regarding friendship features and perceived popularity, a social development goal would be the strongest predictor of positive features in close friendships, whereas a social demonstration-approach goal would be the strongest predictor for perceived popularity. As approach goals, they both might have positive associations with positive outcomes, although it is expected that the relations representing closer alignment of goal content and outcome (i.e., development-quality friendship features and demonstration-approach-popularity) would be stronger. A social demonstration-avoid goal is expected to have negative associations with both friendship features and popularity, although the latter is likely to be stronger in magnitude, as concern about negative judgments may be magnified in public rather than private and more predictable peer settings.

To assess social adjustment, we used both self-reports and teacher reports. Student perceptions are an important aspect of their adjustment (Achenbach, McConaughtly, & Howell, 1987), and much of the research on academic achievement goals of young adolescents has relied on student reports of adjustment (with the exception of report card grades; e.g., Kaplan et al., 2002; Middleton & Midgley, 1997; Skaalvik, 1997). However, given the limitations associated with self-reports (e.g., common method variance explanation for effects), we also asked teachers to assess the aspects of social adjustment that would be visible to them (i.e., prosocial, aggressive, and anxious solitary behavior). Thus, a strength of the present research is the examination of social achievement goals and social adjustment beyond just self-report measures to establish construct validity.

### Method

#### Participants

The participants were sixth-grade students from the same two public middle schools ( $n = 217$  at Wave 1 in December and  $n = 196$  at Wave 2 in March and April) that were used in Experiment 1. Of the 217 students who had Wave 1 data, 181 had Wave 2 self-report data, and 208 had Wave 2 teacher-report data. Thus, the sample for analyses involving self-report social adjustment outcomes was 181, and the sample for analyses involving teacher-report social adjustment outcomes was 208. About two thirds of the sample had previously participated in Study 1. Letters describing the project were sent home, and 84% of the students returned a slip with their parents' written consent for them to participate (resulting in the sample described above). Students reported their gender and ethnicity. The sample was 47% female and ethnically diverse (39% Black, 35% White, 11% Asian, 5% Asian Indian, 4% Hispanic, and 6% other).

## Procedure

Surveys were administered to students in their classrooms by trained researchers. Teachers remained in the classrooms. Social achievement goals and perceived social competence were measured at Wave 1 (December), and social adjustment indices were measured about 3 months later at Wave 2 (March–April). Instructions and items were read aloud while students read along and responded. Students were told that the survey was not a test, that there were no right or wrong answers, and that the purpose of the survey was to find out students' beliefs and behaviors at school. Students were assured that the information would be kept confidential. In addition, students were told that filling out the survey was voluntary; if at any point they wanted to stop, they could do so.

Teachers were asked to complete a brief survey about students' behavior in school at Wave 2. Teachers were told that the purpose of the survey was to better understand students' adjustment to middle school; their participation was voluntary and their responses confidential. In middle schools, students have several different teachers throughout the school day. Thus, we had two different teachers (of main academic subjects) provide independent assessments for a more complete assessment of student behavior in middle school.

## Measures

**Social achievement goals.** We developed new items to measure the three social achievement goals during early adolescence. Social development goal items focus on developing social competence. Social demonstration-approach goal items focus on demonstrating social desirability and gaining positive judgments from others. Social demonstration-avoid goal items focus on demonstrating that one is not socially undesirable and avoiding negative

judgments from others. We reviewed the social goal items Ryan and Shim (2006) used with college students, as well as results of Study 1, to generate items that would be appropriate for young adolescents. We did some pilot testing of a larger pool of potential social goal items for young adolescents and ultimately settled on the 18 goal items reported in Table 3. Conceptually, the new items were parallel to Ryan and Shim, but the wording needed to be different to be appropriate for young adolescents. Of our 18 items, 2 items were identical, 3 items were slightly adapted, and 13 items were new compared to the scale used by Ryan and Shim for college students. All items were rated on a scale that ranged from 1 (*not at all true of me*) to 5 (*very true of me*). Factor and reliability analysis is presented in the Results section.

**Perceived social competence.** Eccles's measure of perceived competence for the social domain was used (Lord, Eccles, & McCarthy, 1994). There were four items, which were rated on a scale that ranged from 1 (*not at all good*) to 5 (*very good*). Sample items are "Compared to most sixth-grade students, how would you rate your social skills?" and "How good are you at making friends?" The measure was reliable in our sample ( $\alpha = .82$ ).

**Prosocial behavior.** Prosocial behavior was assessed with a measure adapted from Cassidy and Asher (1992) and Crick (1996), and consisted of five items: "friendly," "helpful," "cooperative," "kind," and "considerate." Teachers and students rated the items on a scale that ranged from 1 (*never*) to 5 (*always*). The correlation between the two teacher ratings for each student was  $r = .51, p < .05$ . Students' score on the teacher-reported measure was the average of the two teacher reports. The measure was reliable in our sample ( $\alpha = .91$  and  $.84$ , for teacher-reported scale and student-reported scale, respectively).

**Overt aggressive behavior.** Overt aggressive behavior was assessed with the Aggression subscale of the Interpersonal Com-

Table 3  
Factor Loadings for Social Achievement Goals

Item	Social development	Social demonstration-approach	Social demonstration-avoid
I like it when I learn better ways to get along with friends.	.87		
I feel successful when I learn something new about how to get along with other kids.	.83		
I try to figure out what makes a good friend.	.73		
One of my goals is that my friendships become even better over time.	.71		
It is important to me to learn more about other kids and what they are like.	.64		
In general, I try to develop my social skills.	.62		
It is important to me that other kids think I am popular.		.90	
It is important to me to have "cool" friends.		.85	
I want to be friends with the "popular" kids.		.75	
It is important to me to be seen as having a lot of friends.		.75	
I try to do things that make me look good to other kids.		.62	
My goal is to show other kids how much everyone likes me.		.55	
I try not to do anything that might make other kids tease me.			.74
It is important to me that I don't embarrass myself around my friends.			.72
I try to avoid doing things that make me look foolish to other kids.			.66
When I am around other kids, I don't want to be made fun of.			.59
When I am around other kids, I mostly just try not to goof up.			.53
One of my main goals is to make sure other kids don't say anything bad about me.			.47
Eigenvalue	2.42	7.32	1.57
% of variance explained	11.17	38.28	6.23
$\alpha$	.87	.89	.84

Note. Factor loadings above .30 are shown.

petence Scale (Cairns, Leung, Gest, & Cairns, 1995) and consisted of three items: "fights with others," "argues with others," and "gets in trouble." Teachers and students rated the items on a scale that ranged from 1 (*never*) to 5 (*always*). The correlation between the two teacher ratings for each student was  $r = .71, p < .05$ . Students' score on the teacher-reported measure was the average of the two teacher reports. The measure was reliable in our sample ( $\alpha = .88$  and  $.73$ , for teacher-reported scale and student-reported scale, respectively).

*Anxious solitary behavior.* Anxious solitary behavior was adapted from Gazelle's measure (Gazelle & Ladd, 2003; Gazelle & Rudolph, 2004) and consisted of six items: "worries," "anxious," "self-conscious," "shy and timid," "withdrawn from peers," and "prefers to be alone." Teachers and students rated the items on a scale that ranged from 1 (*never*) to 5 (*always*). The correlation between the two teacher ratings for each student was  $r = .69, p < .05$ . Students' score on the teacher-reported measure was the average of the two teacher reports. The measure was reliable in our sample ( $\alpha = .81$  and  $.72$  for teacher-reported scale and student-reported scale, respectively).

*Social worry.* We assessed students' worry regarding their social behavior and relationships with a measure used by Ryan and Shim (2006). Students were directed to write a number from 1 (*not at all true of me*) to 5 (*very true of me*) on the line next to various statements about academic and social worries. The four statements regarding social worries (e.g., "I worry about what my friends think of me" and "Many social situations make me worry") were averaged together such that a high score indicated higher levels of social worry. The measure was reliable in our sample ( $\alpha = .83$ ).

*Positive friendship quality.* We used Rose's (2002) adapted version of Parker & Asher's (1993) Friendship Quality Questionnaire to measure students' perceptions of their positive relationship qualities with their best friend at school. To facilitate a focus on one best friendship, we instructed students to write down the name of their very best friend at school and think of that best friend as they completed items about support (e.g., "Gives advice with figuring things out," 3 items), validation (e.g., "Makes me feel good about my ideas," 2 items), intimacy (e.g., "We can talk about whatever happens to us," 3 items), and conflict resolution (e.g., "We can talk about how to get over being mad at each other," 2 items). All items were rated on a scale that ranged from 1 (*never*) to 5 (*always*). These 10 items formed one factor in a factor analysis and thus were averaged to form one scale. The measure was reliable in our sample ( $\alpha = .89$ ).

*Popularity.* We measured perceived popularity with the Popularity subscale of the Interpersonal Competence Scale (Cairns et al., 1995) consisting of three items ("popular with boys," "popular with girls," and "has lots of friends"). All items were rated on a scale that ranged from 1 (*never*) to 5 (*always*). The measure was reliable in our sample ( $\alpha = .78$ ).

## Results

### Exploratory Factor Analyses

Since these were new items that had never been tested in this age group before, we conducted an exploratory factor analysis. A principal axis factor analysis with oblimin rotation was conducted for the entire sample ( $N = 217$ ) on the 18 social goal items at

Wave 1. Oblimin rotation was appropriate because we assumed the factors would be correlated. Factors whose eigenvalues were greater than 1 were extracted. The analysis yielded three factors that accounted for 55.69% of the total variance (see Table 3). The three factors corresponded to the three hypothesized social goals: social development, social demonstration-approach, and social demonstration-avoid goals. All factor loadings were above .47 on their primary factor. No items loaded on another factor at greater than .30.

### Reliability Analyses

Reliability analyses indicated that the three social achievement goal scales had good internal consistency (see Table 3). The six items in each of the three scales were averaged to create three social achievement goal scales with a range of 1 through 5.

### Correlations Between Social Achievement Goals and Perceived Social Competence

As expected, there was a correlation between the two demonstration goals ( $r = .57, p < .001$ ; see Table 4). As expected, there was a correlation between the two approach goals ( $r = .36, p < .01$ ). Unexpectedly, there was also a correlation between development and demonstration-avoid goals ( $r = .44, p < .001$ ). As expected, perceived social competence was related to both a development goal ( $r = .40, p < .01$ ) and a demonstration-approach goal ( $r = .28, p < .01$ ). In contrast to the hypothesized negative relation between perceived social competence and a demonstration-avoid goal, a positive relation was documented ( $r = .16, p < .05$ ).

### Regression Analyses: Examining Social Achievement Goals as Predictors of Subsequent Social Adjustment (Self-Report Measures)

*Overview of analyses.* Separate multiple regression analyses were conducted for each of the six self-report dependent variables: prosocial behavior, aggressive behavior, solitary anxious behavior, social worry, best-friend quality, and popularity (see Table 5). Social achievement goals and perceived social competence (measured at Wave 1), as well as gender, were entered as predictor variables. Preliminary analyses tested interactions between social demonstration goals and perceived social competence as well as interactions among social goals (i.e., Development  $\times$  Demonstration-Approach, Development  $\times$  Demonstration-Avoid, and Demonstration-Avoid  $\times$  Demonstration-Approach). Additionally, we examined whether gender moderated any of the effects. We used procedures outlined by Aiken and West (1991) to test and interpret interactions. Main effect terms were standardized before computing interaction terms to avoid multicollinearity and aid interpretation of beta coefficients. Significance of interactions was determined if the  $R^2$  increased by a significant amount and if the beta coefficient for the interaction term was significant as well. Only significant interaction terms (by both criteria) were retained in the final models (thus the final models varied for different dependent variables). To interpret the significant interactions, we calculated the predicted values using unstandardized regression coefficients and conducted simple slope tests. Graphs were created

Note. Correlations above .14 are significant at .05 level; above .18 are significant at .01 level. SR = self-report measures; dem-ap. = demonstration-approach; dem-av = demonstration-avoid; perc'd social comp. = perceived social competence; TR = teacher-report measures.

using the predicted values of outcome variables for the students with goal scores one standard deviation above and below the mean.

**Prosocial behavior.** The regression of prosocial behavior on the model yielded significant effects for the final model,  $F(5, 169) = 12.48, p < .001, R^2 = .27$ . There were significant relationships for development and demonstration-approach goals but not for a demonstration-avoid goal. A development goal was positively related to prosocial behavior ( $\beta = .30, p < .001$ ), whereas a demonstration-approach goal was negatively related to prosocial behavior ( $\beta = -.40, p < .001$ ). Perceived social competence was also a significant predictor of prosocial behavior ( $\beta = .36, p < .001$ ).

**Aggressive behavior.** The regression of aggressive behavior on the model yielded significant effects for the final model,  $F(10, 164) = 3.93, p < .001, R^2 = .17$ . There were main effects for each of the three goals that were qualified by significant interaction terms. A significant interaction between a social demonstration-approach and a development goal ( $\beta = -.22, p < .05$ ) indicated that the positive relation between a social demonstration-approach goal and aggressive behavior was not significant when a social development goal was high (see Figure 1). There was also a three-way interaction between a social demonstration-avoid goal, perceived social competence, and gender ( $\beta = .27, p < .01$ ). For girls with high levels of perceived social competence, a social

Table 5

*Standardized Regression Coefficients for Predicting Self-Reports of Social Adjustment at Wave 2 From Social Achievement Goals and Perceived Social Competence at Wave 1*

Variable	Prosocial behavior	Aggressive behavior	Anxious solitary behavior	Social worry	Best-friend quality	Perceived popularity

DAP × DAV				-.27***		
DAV × PSC × Gender		.27**				
DAV × PSC		.06				
DAV × Gender		-.07				
PSC × Gender		.07				

Note. As suggested by Aiken and West (1991), only significant interaction terms were retained in final models. Lower order two-way interaction terms were included to properly examine the three-way interaction term. Thus, final models varied for each outcome. The standardized regression coefficients shown are from the final model with all main effects and interaction terms in the model. When the interaction terms were added to the models, they explained 7%, 7%, and 2% additional variance (all significant at  $p < .05$ ) for aggressive behavior, social worry, and perceived popularity, respectively. DEV = social development goal; DAP = social demonstration-approach goal; DAV = social demonstration-avoid goal; PSC = perceived social competence.

<sup>a</sup> Gender is coded 1 = female and 0 = male.

\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

Figure 1. Social Demonstration-Approach (DAP)  $\times$  Development (DEV) goal interaction on aggressive behavior.

demonstration-avoid goal was positively related to subsequent aggressive behavior. For girls with low levels of perceived social competence and boys of all levels of perceived social competence, a social demonstration-avoid goal was negatively related to subsequent aggressive behavior (see Figure 2).

**Anxious solitary behavior.** The regression of anxious solitary behavior on the model yielded significant effects for the final model,  $F(5, 157) = 4.15, p < .01, R^2 = .12$ . There was a significant relationship for a demonstration-avoid goal, but not for

development and demonstration-approach goals. A demonstration-avoid goal was positively related to anxious solitary behavior ( $\beta = .20, p < .05$ ). Perceived social competence was also a significant negative predictor of anxious solitary behavior ( $\beta = -.32, p < .001$ ).

**Social worry.** The regression of social worry on the model yielded significant effects for the final model,  $F(6, 167) = 6.69, p < .001, R^2 = .19$ . There was a main effect for a demonstration-avoid goal that was qualified by a significant interaction term ( $\beta =$

Figure 2. Social Demonstration-Avoid (DAV)  $\times$  Perceived Social Competence  $\times$  Gender interaction on aggressive behavior. PSC = perceived social competence.

-.27,  $p < .001$ ). A significant Demonstration-Avoid Goal  $\times$  Demonstration-Approach Goal interaction indicated that the positive relation between a social demonstration-avoid goal and social worry was only found when a social demonstration-approach goal was low; there was no relation when a social demonstration-approach goal was high (see Figure 3). However, as can also be seen in Figure 3, a social demonstration-approach goal alone can also result in high social worry. The only significant difference between groups was that students low in both demonstration goals were lower than the other groups. Thus, students with a high level of one or both of the demonstration goals had similar levels of worry, which was higher compared to students with low levels of both types of demonstration goals.

**Best-friend quality.** The regression of best-friend quality on the model yielded significant effects for the final model,  $F(5, 166) = 11.13$ ,  $p < .001$ ,  $R^2 = .25$ . There was a significant relationship for a development goal, but not for demonstration-approach and demonstration-avoid goals. A development goal was positively related to best-friend quality ( $\beta = .17$ ,  $p < .05$ ). Perceived social competence was also a significant predictor of best-friend quality ( $\beta = .33$ ,  $p < .001$ ), as was gender ( $\beta = .24$ ,  $p < .01$ ).

**Perceived popularity.** The regression of perceived popularity on the model yielded significant effects for the final model,  $F(6, 168) = 25.20$ ,  $p < .001$ ,  $R^2 = .47$ . A demonstration-approach goal was positively related to perceived popularity ( $\beta = .28$ ,  $p < .001$ ). There was a significant interaction between development and demonstration-avoid goals ( $\beta = -.13$ ,  $p < .05$ ). A social development goal was related to subsequent perceptions of popularity. However, this hypothesized positive relation was only found when a social demonstration-avoid goal was low; there was no relation when a social demonstration-avoid goal was high (see Figure 4). Perceived social competence was also a significant predictor of perceived popularity ( $\beta = .55$ ,  $p < .001$ ).

#### Regression Analyses: Examining Social Achievement Goals as Predictors of Subsequent Social Adjustment (Teacher-Report Measures)

**Overview of analyses.** Separate multiple regression analyses were conducted for each of the three teacher-report dependent variables with the same model-building procedures as described for the self-reported adjustment indices. Most of the main effects

Figure 3. Social Demonstration-Avoid (DAV)  $\times$  Demonstration-Approach (DAP) interaction on social worry.

Figure 4. Social Development (DEV)  $\times$  Demonstration-Avoid (DAV) goal interaction on perceived popularity.

found for self reports of social adjustment were replicated with teacher reports of social adjustment (see Table 6).

**Prosocial behavior.** The regression of teacher-reported prosocial behavior on the model yielded significant effects for the final model,  $F(5, 194) = 2.86$ ,  $p < .05$ ,  $R^2 = .07$ . There were significant relationships for a demonstration-approach goal but not for development or demonstration-avoid goals. A demonstration-approach goal was negatively related to prosocial behavior ( $\beta = -.26$ ,  $p < .01$ ). Perceived social competence ( $\beta = .15$ ,  $p < .05$ ) was also a significant predictor of prosocial behavior.

**Aggressive behavior.** The regression of teacher-reported aggressive behavior on the model yielded significant effects for the final model,  $F(5, 194) = 3.26$ ,  $p < .01$ ,  $R^2 = .08$ . There were significant relationships for demonstration-approach and demonstration-avoid goals, but not for a development goal. A demonstration-approach goal was positively related to aggressive behavior ( $\beta = .31$ ,  $p < .01$ ), whereas a demonstration-avoid goal was negatively related to aggressive behavior ( $\beta = -.27$ ,  $p < .01$ ).

**Anxious solitary behavior.** The regression of teacher-reported anxious solitary behavior on the model yielded significant effects for the final model,  $F(5, 194) = 2.72$ ,  $p < .01$ ,  $R^2 = .07$ . There were significant relationships for demonstration-approach and demonstration-avoid goals, but not for a development goal. A demonstration-avoid goal was positively related to anxious solitary

behavior ( $\beta = .21, p < .01$ ), whereas a demonstration-approach goal was negatively related to anxious solitary behavior ( $\beta = -.24, p < .05$ ).

### Discussion

The results from Study 2 supported the hypothesized model of social achievement goals. A face-valid measure of social achievement goals was developed and administered to young adolescent students. As expected, factor analyses indicated a three-factor model (social development, social demonstration-approach, and social development-avoid goals). Reliability analyses indicated that the social achievement goal measures have good internal consistency. Social achievement goals were important in explaining subsequent social adjustment. Effects for social achievement goals were independent of perceived social competence and gender. As expected, a distinct pattern of effects was found for each social achievement goal, consistent with the premise that different achievement goals set in motion different cognitive, affective, and behavioral processes. For several aspects of social adjustment, there were significant interactions among goals, indicating that social achievement goals must be considered jointly for a full understanding of their implications for social adjustment.

Results with self-report measures of social adjustment were consistent with the hypothesis that a social development goal would be associated with increased prosocial behavior, decreased aggressive behavior, and increased perceptions of positive qualities in close friendships. A focus on developing social competence seems to be a positive orientation toward the social world that sets in motion adaptive beliefs and behaviors. A social development goal was also related to subsequent perceived popularity, but only when a social demonstration-avoid goal was low, indicating that when a student is focused on both goals, the drawbacks of a social demonstration-avoid goal neutralize the benefits of a social development goal. It is interesting that a social development goal was not associated with teacher ratings of social behavior, as expected. Teachers and students attend to and see different things in the classroom, so this finding may reflect that prosocial behavior associated with a social development goal is more prevalent in peer interactions in situations that are not salient to teachers. Future work could examine peer ratings of prosocial behavior to determine if development goals manifest themselves in certain patterns of behavior that are observed by peers.

A social demonstration-approach goal was positively associated with aggressive behavior and negatively associated with prosocial behavior. This pattern was found for both self and teacher reports of behavior. As expected, a social demonstration-approach goal was positively related to perceived popularity. Collectively, these results suggest that the pursuit of positive judgments by peers as cool or popular may be associated with unprincipled behavior. Interestingly, for self reports, a social development goal ameliorated the positive relation between a social demonstration-approach goal and aggressive behavior. This suggests that an additional benefit of a social development goal is that it can minimize the aggressive behavior that is associated with a social demonstration-approach goal.

The unexpected negative relation between a social demonstration-approach goal and prosocial behavior in the regression models is troubling. This pattern suggests that "nice" behavior

is incompatible with the climb to the top of the social pyramid in middle school. According to both self and teacher reports of behavior, when students are focused on demonstrating social desirability, they are less likely to act in helpful, cooperative, and kind ways toward their peers. Previous research has found that high-status children display both aggressive and prosocial behavior (Hawley, 2003; LaFontana & Cillessen, 2002; Rose et al., 2004). The different results found in our study may reflect that we are examining behaviors associated with the goal for high social status, not behavioral correlates of social status already achieved. A contribution of the present research to the emerging literature on aggressive high-status youth is the focus on antecedent psychological variables of social status. An achievement goal perspective is informative about the developmental precursors of different social behaviors in achieving status in school.

A social demonstration-avoid goal was positively associated with subsequent anxious solitary behavior. This was true for both self and teacher reports of anxious solitary behavior, which provides convincing evidence that a focus on avoiding negative judgments from peers is associated with social behaviors that undermine social adjustment in middle school. Further, endorsement of a social demonstration-avoid goal was also negatively associated with subsequent self-ratings of popularity. A social demonstration-avoid goal had a null relation with positive features in close friendships, indicating that in familiar, private friend relations, an avoid orientation did not undermine the development of qualities such as intimacy and support.

An interaction between a social demonstration-avoid and a social demonstration-approach goal indicated that a focus on either goal was associated with increased social worry. It is interesting that there seems to be a threshold effect whereby focusing on both types of demonstration goals does not relate to higher levels of social worry compared to students who focused on only demonstration-approach or demonstration-avoid goals. Thus, when students are focused on others' opinions of them, that focus is associated with social worry, regardless of whether they are oriented toward garnering positive judgments or avoiding negative judgments, or both.

There was another interaction involving a social demonstration-avoid goal, perceived social competence, and gender. A social demonstration-avoid goal was related to aggressive behavior, although the relation was moderated by the level of perceived social competence and gender. For socially confident girls, a social demonstration-avoid goal was positively associated with aggressive behavior; whereas for socially unconfident girls and all boys, a social demonstration-avoid goal was negatively associated with aggressive behavior. This suggests that aggressive behavior for girls may have two different sources: desire for high social status, and concern about low social status. However, the latter results in aggressive behavior only if a girl views herself as socially skilled. The effect size for this interaction was small (.08), so it will be important for future research to replicate this finding. Future work that investigates relational aggression, in addition to overt aggression, might also provide additional information regarding gender differences in how social achievement goals manifest themselves in behavior among peers (Cillessen & Mayeux, 2004; Rose et al., 2004). It may be that gender differences in behaviors such as gossiping or rumor spreading are part of the explanation for the

increased aggressive behavior for socially skilled yet socially demonstration-avoidant girls.

Notably, the documented effects for social achievement goals were independent of perceived social competence. Thus, orientations to social competence explained variation in social adjustment above and beyond perceived social competence. As expected, approach social achievement goals had positive correlations with perceived social competence. Unexpectedly, a social demonstration-avoid goal had a small positive correlation with perceived social competence (although weaker than both approach goals). Perhaps a social demonstration-avoid goal is more related to other early adolescent issues (i.e., new social setting, puberty, and imaginary audience concerns) than perceived social competence. A social demonstration-avoid goal may, in part, reflect a strategic approach to navigating the social scene of a new school; that may be why there is a positive correlation with perceived social competence in our sample. In addition, correlations among goals revealed an interesting pattern for a social demonstration-avoid goal. Although positively correlated with a social demonstration-approach goal as expected, a social demonstration-avoid goal was also correlated with a social development goal. Although not unprecedented in the academic domain, this is less common. Thus, in general, the results indicate that the nature of achievement goals in the social domain is similar to other domains; however, there may be some differences in the nature of achievement goals between the social and academic domains.

### General Discussion

The present research establishes that young adolescents' different orientations toward developing or demonstrating social competence are an important element of social motivation in middle school. Although young adolescents are often concerned with validation and approval from peers (i.e., demonstration goals), they are also often oriented toward personal standards of developing themselves in their social world (i.e., development goals). Further, the distinction between garnering positive feedback from others and avoiding negative feedback from others is important (i.e., demonstration-approach vs. demonstration-avoid goals). Thus, an achievement goal approach is a facet of young adolescents' social motivation that has been generally overlooked.

We do not suggest that social achievement goals are the most critical or salient aspect of social motivation. They may be consequential because, as young adolescents accomplish or fail at the host of social goals that have been highlighted in previous research (intimacy, fun, etc.), they evaluate their social competence. The judgments early adolescents make of themselves and the processes that unfold are likely to be intimately related to their social achievement goals. Future work that examines the relations between other social goals that have been found to be important (e.g., intimacy, revenge, responsibility) and social achievement goals may further our understanding of social motivation during early adolescence.

Future research may also expand our understanding of social achievement goals, perceived social competence, and social adjustment by following students over a longer period of time and examining a wider array of adjustment indices. The implications of social achievement goals, as well as perceived social competence, may be different when considered in light of long-term develop-

ment. The nature and consequences of social achievement goals may vary at different stages of life. Although it seems that a social development goal would be adaptive and a social demonstration-avoid goal maladaptive at any age, a social demonstration-approach goal may not be associated with aggressive behavior at younger ages, when perhaps the peer culture is not as supportive of such behavior (LaFontana & Cillessen, 2002; Rose et al., 2004). In addition, the present research is correlational and cannot make conclusions about causality. Future work that examines causal relations, especially as affected by development, would be informative.

Further, future research with friend reports and peer nomination measures could provide another perspective on students' behaviors within school. Whereas students and teachers provide valid information regarding social adjustment, peers can provide insight into aspects of behavior that self and teacher reports cannot (e.g., whether relationships are reciprocated and how students' reputation stands among peers at school). For example, examining different measures of social status (sociometric popularity and peer perceptions of popularity) could be informative. Measures of sociometric popularity ask students about peers they like or do not like and thus indicate likeability. Measures of peer-perceived popularity ask students about who is popular or cool and thus indicate social status and centrality (Cillessen & Rose, 2005). Our results suggest that a social development goal would be associated with wide likeability, whereas a social demonstration-approach goal would be associated with a popular reputation.

As achievement goals have been shown to be influenced by features of the context (see Elliot, 2005, for a review), this line of research may have implications for creating middle school environments that promote social adjustment. Further, results from research concerning social achievement goals may be integrated with results concerning academic achievement goals and aid in making recommendations that simultaneously promote academic and social adjustment. As teachers are overwhelmed with numerous problems and issues, identifying key factors that might support multiple aspects of adjustment is important. Early adolescence marks the beginning of a downward trend in academic and social adjustment for many children (Juvonen et al., 2004). Researchers across many disciplines, as well as educators and parents, have become increasingly concerned about adjustment during early adolescence. The research reported here takes an initial step toward using a common framework (i.e., applicable to academic, athletic, and social domains) to better understand social adjustment during early adolescence with the hope that such an approach will ultimately contribute to knowledge that may help all students reach their potential in middle school.

Previous studies in education have inspected the relations between students' autonomous versus controlled motivation and relevant outcomes. In most of those studies a global index of self-determined motivation was created. The purpose of this article was to examine (a) how the different types of motivation proposed by Self-Determination Theory combine into distinct profiles as identified by cluster analysis and (b) the links between those profiles and objective criteria of achievement. In Study 1, motivation toward physical education was assessed at the beginning of a 10-week gymnastics teaching cycle, and performance was assessed at the end of the cycle among a sample of high school students ( $N = 210$ ). Study 2 ( $N = 215$ ) extended Study 1 by controlling students' initial performance, measuring the effort they exerted and recording their grades. Cluster analyses revealed three motivational profiles: self-determined, non-self-determined, and moderate levels of both types of motivation. Path analysis showed that the self-determined profile was related to the highest achievement. The results are discussed in terms of their implications for the assessment of students' motivation and the consequences of motivational profiles for educational outcomes.

**Keywords:** self-determination theory, motivational profile, achievement

The importance of motivation in education is unquestionable. As decades of research in educational settings have stressed, motivation is a consistent and significant contributor to students' functioning and performance (Good & Brophy, 2000). However, throughout the past 20 years, research using the framework of Self-Determination Theory (SDT; Deci & Ryan, 1985, 2000; Vallerand, 1997) has shown that individuals in general, and students in particular, differ considerably in the ways that they could be motivated toward an activity. More important, those differences in individuals' motivational orientations have far-reaching influences on their approach to an activity and the consequences that follow (see Deci & Ryan, 2000, for a review). This comprehensive framework holds the potential to contribute significantly to our

understanding of the issues related to motivation in education for the following reasons. First, it distinguishes between different types of motivation that can have a distinct impact on the maintenance and integration of behavior. Second, it presents clear hypotheses regarding the conditions that should hinder or facilitate students' motivation. Third, it outlines various consequences (cognitive, affective, and behavioral) that are associated with the different types of motivation (Vallerand, 1997). Fourth, it addresses the issue of internalization, the process by which behaviors that were initially reinforced by external sources (e.g., parents or teachers) become integrated within the individual to form a permanent part of his or her self.

In spite of the tremendous progress that has been made in this area of inquiry, some of the more basic questions concerning motivation conceptualization and measurement have remained relatively unexamined. One of the unexplored issues concerns the representation of the multiple forms of motivation proposed by SDT. Few studies have examined how these different goals combine to influence students' achievement behavior. In this article, we used cluster analysis in order to examine how the different forms of motivation proposed by SDT combine with each other and how they relate to students' academic performance in physical education (PE) classes. Two prospective studies were conducted in order to look at the links between the motivational profiles observed in a natural class setting and objective achievement criteria such as performance, overt effort, and grade. In the next part, we present the different motivational orientations assumed by SDT, as well as the links observed between those constructs and various academic outcomes. Then we explain how the different types of

motivation have been used in past literature and the problems that arise. Finally, we present the specific purposes of the two studies.

### The SDT Motivational Continuum

Research clearly supports the idea that individuals have different motivational orientations. They can be intrinsically motivated, when they are engaging in activities for their inherent satisfaction; extrinsically motivated, when they are engaging in activities for instrumental reasons; or amotivated, when they prove no regulation toward an activity. According to research, intrinsic motivation (IM) could derive from several sources. For instance, Vallerand (1997; Vallerand, Blais, Brière, & Pelletier, 1989) distinguished between IM to experience stimulation, when individuals are motivated by feeling pleasant sensations; IM toward knowledge, when they are moved by the desire to explore and learn new things; and IM toward accomplishment, when they aim at improving themselves.

Research has also supported distinctions regarding the different types of motivation that fall in the category of extrinsic motivation. The first two forms of extrinsic motivation are labeled, respectively, *external*, when the individuals' behavior is controlled by external sources, and *introjected*, when individuals have internalized the formerly external source of motivation but have not yet truly accepted the behavior. For these reasons, they are referred to as non-self-determined or controlled. The next two kinds of extrinsic motivation, on the other hand, represent self-determined, or autonomous, types of regulation. A distinction is made between identified regulation, which refers to a situation in which individuals perform an activity that has personal importance, and integrated regulation, in which individuals have integrated a behavior within their set of goals and values. Finally, the lowest level of self-determination proposed by SDT is amotivation. Amotivated individuals lack perceived competence because they do not feel able to perform the behavior, or they lack perceived control because they think their actions will not be adequate or sufficient to achieve a desired outcome (Deci & Ryan, 2000).

### The Outcomes of Motivation

A considerable amount of research has examined the relations between the different types of motivation and positive and negative outcomes. It has been observed that IM and self-determined forms of extrinsic motivation (i.e., identified and integrated regulations) have been linked to the more positive outcomes, whereas non-self-determined forms of motivation (i.e., external and introjected regulations) and amotivation have been linked to the less positive ones (Ryan & Deci, 2000; Vallerand, 1997). In education, there is evidence since the early 1990s that self-determined motivation toward school is related to several important outcomes (for reviews, see Deci, Vallerand, Pelletier, & Ryan, 1991; Reeve, 2002), including students' level of achievement (e.g., Burton, Lydon, D'Alessandro, & Koestner, 2006; Miserandino, 1996), coping style (e.g., Ryan & Connell, 1989), preference for optimal challenges (e.g., Boggiano, Main, & Katz, 1988), creativity (e.g., Amabile, 1985), well-being (Levesque, Zuehlke, Stanek, & Ryan, 2004), and persistence for a class (Vallerand & Bissonette, 1992) and for school (Vallerand, Fortier, & Guay, 1997).

Although research has been scarcer in the physical activity context, a growing body of research has confirmed this pattern of

results in that domain. Self-determined motivation has been linked to higher levels of self-reported effort in sport (Pelletier et al., 1995) and exercise (Fortier & Grenier, 1999) and to lower levels of sport dropout (Pelletier, Fortier, Vallerand, & Brière, 2001; Sarrazin, Vallerand, Guillet, Pelletier, & Cury, 2002). Also, self-determined motivation for physical education has been linked to the intention of being physically active or playing sports in the future (e.g., Ntoumanis, 2001; Standage, Duda, & Ntoumanis, 2003); to concentration, positive affect, and preference for challenging tasks (Standage, Duda, & Ntoumanis, 2005); to self-reported (Goudas, Biddle & Underwood, 1995; Ntoumanis, 2001, 2002) or teacher-reported effort (Ferrer-Caja & Weiss, 2000; Standage, Duda, & Ntoumanis, 2006); and to persistence and performance (Vansteenkiste, Simons, Lens, Sheldon, & Deci, 2004, Study 3); it has been negatively linked to boredom (Ntoumanis, 2001, 2002) or feelings of unhappiness (Standage et al., 2005).

### The Operationalization of Motivation

In order to test the SDT hypotheses, researchers have been faced with some crucial questions about the best ways to use the different types of motivation as determinants of various outcomes. Generally, correlational or experimental methods were used to examine relations between single goals and criterion measures (e.g., Ryan & Connell, 1989; Vansteenkiste et al., 2004). Sometimes, multiple regression analyses or structural equation modeling were used in order to test if goals have independent and additive effects for achieving a particular outcome (e.g., Ntoumanis, 2001; Pelletier et al., 2001). Finally, a major part of the studies integrated the scores obtained for the different types of motivations into a Self-Determination Index (e.g., Ryan & Connell, 1989). This index relies on an interactional hypothesis (Vallerand & Fortier, 1998), according to which intrinsic and extrinsic motivations are not independent, and a high level of one kind of regulation is necessarily linked to a low level of the other. The Self-Determination Index is generally calculated by giving each subscale a specific weight according to its respective place on the self-determination continuum (i.e., +3 +2, +1, -1, -2, and -3, respectively, for IM, integrated regulation, identified regulation, introjected regulation, external regulation, and amotivation scales). Next, the weighted scores of each subscale are added to derive a single index (e.g., Levesque et al., 2004; Miserandino, 1996; Vallerand et al., 1997). An important element in favor of the Self-Determination Index is the support for a matrix simplex in the continuum of self-determination. A matrix simplex is observed when the correlation between measures of two motivational constructs tends to decrease as the distance between them on the theoretical continuum increases. For example, because of its position on the theoretical continuum of self-determination, IM should be highly correlated with identified regulation but negatively correlated with amotivation. Its correlations with introjected and external regulation should take values comprised between the two others. This pattern of correlations has been observed in several domains, including education (e.g., Vallerand et al., 1993), sport (e.g., Pelletier et al., 1995), and exercise (Li, 1999).

However, several recent studies raised questions concerning the hypothesized motivational continuum, because the correlations among the ordered subscales provided only limited support for the simplex pattern (e.g., Cokley, 2000; Fairchild, Horst, Finney, &

Barron, 2005). For example, Fairchild et al. (2005) found that external regulation score is rather independent from the three intrinsic motivation scores (between .05 and .21). These results support the proposition that intrinsic and extrinsic motivation are not necessarily mutually exclusive, but rather independent constructs (e.g., Amabile, Hill, Hennessey, & Tighe, 1994; Covington & Mueller, 2001; Lepper & Henderlong, 2000). For example, Covington and Mueller (2001) underlined that "the weight of recent evidence suggests that intrinsic and extrinsic tendencies may best be conceived as two independent orientations, not just two endpoints on a single continuum" (p. 163). In this case, as Fairchild et al. (2005) noted, "perhaps one needs to consider how subscales combine or interact to promote motivation" (p. 335).

Little research has been carried out on the various ways to represent and group the different types of motivation proposed by SDT, in spite of the call of certain researchers to examine how they combine into distinct motivational profiles (Vallerand, 1997). This preoccupation is shared by other researchers, such as Sansone and Harackiewicz (2000), who concluded their book on intrinsic and extrinsic motivation by underlining that "the challenge that confronts theorists now is to specify *how* individuals might pursue more than one goal at a time and to detail the motivational dynamics of multiple goal pursuit" (p. 450). In the present article, we propose that a pattern-centered approach is suitable for situations in which several factors might act in conjunction with each other. It is especially the case when moderate or high correlations exist between several factors, which can undermine the efficacy of classical regression approaches (Mosteller & Tukey, 1977).

A particularly useful method of examining this issue is cluster analysis. This statistical technique identifies homogeneous groups, or clusters, on the basis of the shared characteristics they possess (Härdle & Simar, 2003). Therefore, the groupings obtained allow the researcher to examine differences between profiles rather than looking at interindividual differences. This kind of analysis should be helpful to determine if, in conformity with the SDT hypothesis, self-determined or non-self-determined profiles can be observed in natural settings, and/or to determine if, in conformity with the additive hypothesis, motivational profiles combining high levels of self-determined as well as non-self-determined motivation emerge.

Recently, several studies used cluster analysis to examine motivational profiles in the educational (e.g., Braten & Olaussen, 2005; Meece & Holt, 1993; Ntoumanis, 2002; Wang, Chatzisarantis, Spray, & Biddle, 2002), sport (Hodge & Petlichkoff, 2000; McNeill & Wang, 2005; Vlachopoulos, Karageorghis, & Terry, 2000), and physical activity settings (Biddle & Wang, 2003; Marshall, Biddle, Sallis, McKenzie, & Conway, 2002; Wang & Biddle, 2001), some of them having been based on achievement goal theory (e.g., Meece & Holt, 1993), SDT (Ntoumanis, 2002; Vlachopoulos et al., 2000), or a mix of both theories (e.g., Biddle & Wang, 2003; Wang et al., 2002). Two of these studies examined specifically the different motivations proposed by SDT. Vlachopoulos et al. (2000) found, among two large samples of athletes, one profile higher on self-determined forms of motivations and lower on non-self-determined forms of motivation, as well as one profile with relatively high scores on every kind of regulations and low scores on amotivation. None of the obtained profiles showed higher scores on non-self-determined than on self-determined forms of motivations. The researchers suggested that athletes with those profiles may have ceased their sport participation and therefore could not be part of the sample anymore.

The motivational profiles observed by Ntoumanis (2002) in physical education were quite different. In a cross-sectional study, he questioned two samples of British students about their experience in physical education. The questionnaire included self-reported measures of motivational climate, self-determined motivation, effort, enjoyment, and boredom. The data collected in the first school were used to conduct an exploratory cluster analysis, whereas the data from the second school were used to conduct a confirmatory analysis. The same three profiles emerged. In the first profile, students displayed high levels of self-determined motivation but low levels of external regulation and amotivation. In another cluster, students showed low scores for self-determined kinds of motivation, moderate scores for introjection, and high scores for external regulation and amotivation. The third profile was characterized by average scores for every form of regulation. These results have to be interpreted cautiously, however, because antecedent (motivational climate), consequences (e.g., boredom), and motivations were analyzed at the same time. In other words, the profiles observed in this study were not, strictly speaking, motivational profiles, because the numerous variables entered in the analysis may have influenced the results. It seems more appropriate to treat only the motivational scores with such an analysis, and afterwards to examine how the motivational profiles are related to certain important outcomes.

### The Current Studies

With the recent shift in interest for the possible ways to combine the different types of motivation proposed by SDT (i.e., the use of the Self-Determination Index vs. the use of different clusters), a key question concerns the relative predictive power of the different types of motivational profiles that could result from clusters analysis. That is, should motivation researchers who are interested in predicting important outcomes in education, such as involvement, performance, or grade, consider more than one way to combine the different forms of motivation proposed by SDT, and are some ways better suited to the prediction of some outcomes over others?

Accordingly, the purpose of this article was twofold. First, we examined whether the three profiles observed by Ntoumanis (2002) in a sample of British students would emerge among students from another country when only motivational variables in the grouping analysis were considered. The interest of this replication is both theoretical and empirical. From a theoretical perspective, it is not clear yet how the different kinds of motivation proposed by SDT should be combined. If a cluster analysis reveals only self-determined or not self-determined profiles of individuals, this would give support to the hypothesis of a continuum of motivation in the educational context. On the other hand, if cluster analysis reveals students' profiles with high levels of both self-determined and non-self-determined motivation, this would support the hypothesis that those two kinds of motivation can combine in naturalistic settings. Indeed, Lepper and Henderlong (2000) argued that "despite the experimental demonstrations that superfluous extrinsic contingencies *can* undermine intrinsic interest in controlled experimental contexts, [we think that] intrinsic and extrinsic motivation may, in many real-world settings, exert simultaneous positive influences on behavior" (p. 273). From an empirical point of view, there is great interest to know which motivational profiles actually exist in an academic setting like physical education classes and in which proportions students display such profiles.

In line with the findings of Ntoumanis (2002), two clusters coherent with the SDT hypothesis were expected to emerge, that is, where low levels of self-determined forms of motivation would be present with high levels of non-self-determined forms of motivations, and vice versa. We also expected the emergence of a third cluster that would show average levels of every kind of motivation. In order to reach this goal, an exploratory (Study 1) and a confirmatory (Study 2) cluster analysis were conducted on two separate samples of French high school students.

Second, we wanted to examine the consequences that those motivational profiles may have for behavioral variables representative of students' achievement (like effort, performance, and grade). It is important to emphasize that common limitations encountered in several of past studies conducted in education or in physical education were that most of the outcomes were assessed with self-reported measures and that these studies used a cross-sectional design (e.g., Ntoumanis, 2001, 2002; Standage et al., 2003, 2005). One problem with this procedure is that the links observed between self-reported measures from the same source may be inflated by shared variance rather than due exclusively to actual relations. Moreover, the absence of a longitudinal design limits the possibilities of inferring causality among the variables. We thus chose to use objective measures of students' achievement and to adopt a prospective design. In Study 1, we tested whether motivational profile would be linked to final performance, assuming that the more self-determined the profile of a student (i.e., high scores on self-determined scales and low scores on non-self-determined ones), the better would be his or her final performance. In Study 2, we adopted a more complex design in order to examine in more detail the role that motivational profile may play in the achievement process. Insofar as initial motivational profile might not be independent from initial performance, it seemed important to examine the relation between motivational profile and final performance while controlling for students' initial performance if we wanted to reinforce the idea that motivational profile actually has an effect on achievement. Grade and provided effort were also assessed as achievement outcomes.

## Study 1

### Method

#### Participants and Procedure

Two hundreds and ten students (104 girls, 104 boys; 2 students did not specify gender) from a French high school volunteered to participate in the study. They were in sixth-grade ( $N = 73$ ), seventh-grade ( $N = 70$ ), and ninth-grade ( $N = 67$ ) classes.<sup>1</sup> Their ages ranged between 10.7 and 16.8 years ( $M = 13.26$  years,  $SD = 1.49$ ). In France, physical education is a compulsory subject for all high school students. Generally, teachers teach different sports and physical activities in 10-week cycles (i.e., 10 lessons of 2 hr). The study was conducted during gymnastics cycles in scheduled physical education lessons. Prior to the initiation of the research, teachers, parents, students, and school administrators were asked to participate in an observational study. Students' motivations for the activity were assessed during the first lesson. At the end of the cycle, all students were videotaped individually in order to evaluate their performance in gymnastics.

### Measures

**Motivation.** Motivation toward gymnastics was assessed at the beginning of the cycle. An adaptation of French motivation scales in sport (i.e., the "Echelle de Motivations dans les Sports" [EMS], Brière, Vallerand, Blais, & Pelletier, 1995) and in education (i.e., the "Echelle de Motivation Académique," Vallerand et al., 1989), and an adaptation of a scale developed in English to assess physical education motivation (Standage et al., 2006), were used in order to fit both the sportive and educational aspects of physical education. These three tools assessed the multifaceted motivational regulations proposed by SDT. Depending on the subscale, the items were preferentially adapted from one tool or the other. For example, the IM scales were mainly derived from the EMS. The adaptation consisted of minor changes in the wording of some items to target the gymnastics context and/or a translation in French. Six motivational constructs relative to physical education were assessed in an 18-item scale. The participants had to complete the following sentence: "I participate in gymnastics classes" with items reflecting IM to experience stimulation (e.g., "for the excitement I feel when I am really involved in the activity"), IM toward knowledge or accomplishment (e.g., "for the satisfaction I experience while I am perfecting my abilities"),<sup>2</sup> identified regulation (e.g., "because what I learn in this activity will be useful later"), introjected regulation (e.g., "because I would feel guilty if I could not succeed in this activity"), external regulation (e.g., "because that's what I'm supposed to do"), and amotivation (e.g., "I don't know why I go in gymnastics, if I could, I would get exempted"). An English version of the entire scale is presented in Table 1. Responses were made on a 7-point scale ranging from 1 (*strongly disagree*) to 7 (*strongly agree*).

**Performance in gymnastics.** Students' performance in gymnastics was based on a test consisting of five basic gymnastics exercises (e.g., stretched handstand back drop, backward roll, and cartwheel). The students were videotaped one by one during a class prior to the initiation of the gymnastics cycle. Three experts in gymnastics rated the videotaped performance of each student on

<sup>1</sup> In France, high school is comprised of junior high school, which usually includes students who are 11 to 15 years old and between sixth and ninth grades, and senior high school, which includes older students between tenth and twelfth grade. Both of our samples consisted of junior high school students (i.e., those in the four first grades of high school).

<sup>2</sup> Few authors (e.g., Cokley, Bernard, Cunningham, & Motoike, 2001; Fairchild et al., 2005) questioned the distinctiveness of IM toward knowledge and accomplishment subscales, insofar as they appeared very correlated (.86). Results of a pilot study that we carried out with a representative sample of 100 students showed that scores on IM toward knowledge and accomplishment were very correlated ( $\phi = .92$ ). A test of the discriminant validity between the two constructs, which consisted of examining whether the pair of latent factors could be treated as a single construct by setting each correlation to 1.0 and comparing the constrained model with a model in which the correlation was free to vary, revealed that correlation was not significantly different from 1.0 and thereby did not support the discriminant validity of the constructs. Finally, interviews carried out with 10 students of this sample showed that they did not perceive the nuances that could exist between items assessing IM toward knowledge (e.g., "For the pleasure I experience when I learn new skills") and those assessing IM toward accomplishment (e.g., "For the pleasure I experience when I improve some of my weaknesses"). As a result, only three items among the most representative of those subscales have been retained in this study.

Table 1  
*Items of the Motivation Scale With Corresponding Factor Loadings (Study 1): "I participate in gymnastics classes . . ."*

Items	Loadings
IM Toward Stimulation	
For the excitement I feel when I am really involved in the activity	.82
Because this activity is fun	.93
For the emotions I experience while I practice this activity	.87
IM Toward Knowledge or Accomplishment	
For the pleasure I experience when I improve some of my weaknesses	.75
For the pleasure I experience when I learn new skills	.88
For the satisfaction I experience while I am perfecting my abilities	.91
Identified Regulation	
Because what I learn in this activity will be useful later	.80
Because it is important and it can help me for other things	.88
Because this activity is important for my personal growth	.71
Introjected Regulation	
Because I absolutely need to succeed in this activity	.77
Because I would feel bad about myself if I did not	.78
Because I would feel guilty if I could not succeed in this activity	.62
External Regulation	
Because I don't want to disappoint important people	.37
Because I'll get into trouble if I don't do what the teacher's asking	.56
Because that's what I'm supposed to do	.72
Amotivation	
I don't know why I go in gymnastics, if I could, I would get exempted	.69
But it doesn't worth it, I feel that I'm wasting my time	.74
I don't see why we should have gymnastics	.77

*Note.* This table presents an English translation of the French items used in the studies.

a 1 (*low level*) to 7 (*high level*) response scale. Each expert looked at the videotapes individually and made a single global rating of the student's performance after viewing all five exercises. Interjudge reliability was very good ( $\alpha > .90$ ). The mean of the three experts' scores was calculated and used as an indication of students' gymnastics performance. This procedure has been used previously in studies involving physical education classes (e.g., Chanal, Marsh, Sarrazin, & Bois, 2005).

### Data Analysis

First, we carried out a confirmatory factor analysis (using Lisrel 8.54; Jöreskog & Sörbom, 2003) in order to examine the factorial structure of the questionnaire assessing students' motivation. Next, the correlations between motivational scores were examined. Afterwards, an exploratory cluster analysis was conducted in order to examine how many motivational profiles could be identified. An examination of the cluster composition according to gender and school year was then carried out. Finally, an analysis of variance (ANOVA) was done in order to test whether motivational profiles were linked to final performance.

### Results and Discussion

The means and standard deviations of the variables are shown in Table 2, as well as the alpha coefficients and correlations among variables.

#### Confirmatory Factor Analysis

The structure we tested was supposed to rely on six factors, namely the following: IM toward stimulation, IM toward knowledge or accomplishment, identified regulation, introjected regulation, external regulation, and amotivation, with three items expected to load on each factor. A test carried out in order to evaluate the normality of the distribution of the variables revealed that none of them was normally distributed (multivariate skewness and kurtosis tests,  $ps < .0001$ ). We thus chose to use the robust maximum likelihood estimation procedure. The analysis showed a relatively good fit of the six-factor structure with the data,  $\chi^2(120) = 304$ ,  $p < .01$ , robust comparative fit index (CFI) = .97, non-normed fit index (NNFI) = .96, standardized root mean residual (SRMR) = .06, root-mean-square error of approximation (RMSEA) = .07, 90% confidence interval (CI) of RMSEA = .057–.082. The factor loadings were all significant at the

.01 level and ranged between .37 and .93 ( $M = .74$ ). They are presented along with the corresponding items in Table 1.

### Simplex Pattern

Correlations among the constructs are shown in Table 2. The correlations between the variables appear to be in conformity with a simplex ordered matrix, although we found some deviations from this presumed pattern. For example, IM toward knowledge or accomplishment displayed a more important relationship with identified regulation (.75) than with IM toward stimulation (.65). More important, introjected regulation showed strong positive correlations with IM toward stimulation (.52), IM toward knowledge or accomplishment (.62) and identified regulation (.59), no correlation with external regulation ( $-.02$ , *ns*), and only moderate negative correlations with amotivation ( $-.25$ ).

### Cluster Analysis

Given that the internal consistency of each subscale proved to be satisfactory (see Table 2), the average of the scores was calculated for each one. A cluster analysis was conducted next, following the procedure suggested by Hair, Anderson, Tatham, and Black (1998). All the variables included in a cluster analysis have to share the same metric so that each of them contributes equally to the formation of the clusters. All the motivational constructs were assessed on a 7-point

scale. Cluster analysis is also sensitive to outliers. Preliminary analyses showed no cases with a distance from the mean greater than three times the value of the standard deviation. Finally, multicollinearity between variables may impact on the cluster analysis by giving more weight to collinear variables. Given that no Bravais-Pearson correlation coefficient was higher than .90, we considered that there was no problem of this kind (Hair et al., 1998).

A hierarchical cluster analysis was performed using Ward's method with a squared Euclidean distance measure. The agglomeration schedule and dendrogram were used to identify the number of clusters. A high increase of the agglomeration schedule (37%) suggested a three-cluster solution to be suitable. Figure 1 shows the profiles of those three clusters. The first cluster was labeled "self-determined" profile and represented 35% of the sample ( $N = 73$ ). Students in this cluster showed high levels of self-determined forms of motivation (i.e., IM and identified regulation), moderate level of introjected regulation, and low levels of external regulation and amotivation. The second cluster was labeled "moderate" profile and also represented 35% of the sample ( $N = 73$ ). Students in this cluster had average scores for every form of motivation, with a majority of scores close to 3 and 4 on a 7-point scale. The third cluster was labeled "non-self-determined" profile and represented 30% of the sample ( $N = 64$ ). Students in this cluster displayed low levels of self-determined forms of motivation (i.e., IM and identified regulation), a low level of introjected regulation, and relatively high levels of external regulation and amotivation.

Descriptive Statistics for the Three Clusters (Study 1)

Variable	Cluster 1 ( <i>N</i> = 73), self-determined		Cluster 2 ( <i>N</i> = 73), moderate		Cluster 3 ( <i>N</i> = 64), non- self-determined		<i>F</i>	<i>p</i>	$\eta^2$
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>			
1. IM toward stimulation	5.44 <sup>a</sup>	1.29	3.35 <sup>b</sup>	1.43	1.66 <sup>c</sup>	1.03	212.11	.001	.65
2. IM toward knowledge or accomplishment	5.73 <sup>a</sup>	1.25	4.54 <sup>b</sup>	1.10	1.90 <sup>c</sup>	0.91	218.11	.001	.66
3. Identified regulation	4.68 <sup>a</sup>	1.59	3.53 <sup>b</sup>	1.21	1.44 <sup>c</sup>	0.59	131.65	.001	.54
4. Introjected regulation	3.93 <sup>a</sup>	1.53	3.64 <sup>a</sup>	1.37	1.92 <sup>b</sup>	1.05	46.82	.001	.29
5. External regulation	2.21 <sup>a</sup>	1.25	4.19 <sup>b</sup>	1.49	4.22 <sup>b</sup>	1.60	96.15	.001	.46
6. Amotivation	1.53 <sup>a</sup>	1.77	3.52 <sup>b</sup>	1.33	5.00 <sup>c</sup>	1.82	202.71	.001	.64
7. Final performance in gymnastics	4.70 <sup>a</sup>	1.60	3.93 <sup>b</sup>	1.63	3.51 <sup>c</sup>	1.71	5.37	.01	.09

Note. Means in the same row that do not share superscripts differ at  $p < .01$ , using Newman-Keuls post hoc tests. IM = intrinsic motivation.

The clusters' size, as well as the means and standard deviations of their centroid, are shown in Table 3.

A multivariate analysis of variance (MANOVA) showed a significant effect of cluster membership on the six motivational constructs (see Table 3; Wilks's lambda = .13, Rao  $R[12, 404] = 58.29$ ,  $p < .001$ ). Follow-up ANOVAs revealed a significant effect of cluster membership on each motivational construct (the values of  $F$ ,  $p$ , and  $\eta^2$  are indicated in Table 3). Newman-Keuls post hoc analyses ( $p < .01$ ) indicated that the three groups were significantly distinct from each other on all motivational scales, except for introjected regulation between the moderate and self-determined profiles and for external regulation between the non-self-determined and moderate profiles.<sup>3</sup>

### Motivational Profile and Gymnastics Achievement

An ANOVA was carried out in order to test whether motivational profile was linked to different levels of achievement among students, represented by their final performance in the activity. The analysis was significant,  $F(2, 112) = 5.37$ ,  $p < .01$ ,  $\eta^2 = .09$ . Newman-Keuls post hoc analyses ( $p < .01$ ) revealed that the three clusters were distinct on final performance in gymnastics (see Table 3), with students in the self-determined cluster showing the highest average performance ( $M = 4.70$ ), followed by the moderate ( $M = 3.93$ ) and the non-self-determined cluster ( $M = 3.51$ ).<sup>4</sup>

Globally, this result is coherent with the tenets of SDT and with previous research in education (e.g., Reeve, 2002). However, the result relative to introjected regulation is somewhat surprising. As a non-self-determined form of regulation, it is theoretically assumed to lead to negative consequences. In the present study, it was found to be linked to better achievement. In the sport context, introjection has been found previously to be related to short term persistence (Pelletier et al., 2001) but not to long-term persistence. Perhaps it deserves to be considered a potential positive form of motivation at a short-term level.

This study also revealed the existence of a third motivational profile, which comprises students with moderate scores for all motivational scales. It thus seems possible to combine both self-determined and non-self-determined forms of motivation when they remain moderately developed. The analysis did not show a profile with high scores on the majority of subscales. The analyses showed that students with this moderate profile globally realized

better performances than did students with a non-self-determined profile, but poorer performances than students with a self-determined profile.

Even if a prospective design was adopted in this study, the correlational nature of the data does not allow us to affirm that the different motivational profiles observed were the cause for different levels of performance at the end of the cycle. In other words, we cannot ignore the possibility that differences in initial performance are responsible for the motivational profiles observed. It thus seemed important to control for initial performance in order to evaluate more accurately the potential impact of motivation on final performance. Moreover, criteria other than performance should also be used as representative of achievement.

### Study 2

The first aim of Study 2 was to verify that the motivational profiles observed in Study 1 could be validated in another sample of students. The second aim was to test the effect that those motivational profiles may have on performance, controlling for initial performance, as well as the role that these variables and exerted effort may play in the prediction of final grade.

According to SDT, it was hypothesized that the more self-determined the profile of the students, the greater their effort,

<sup>3</sup> Chi-squared tests of association were conducted in both studies to examine the possible link between cluster membership and gender or school year. The analyses revealed no association between students' gender and cluster membership. On the other hand, school year tended to be related to cluster membership in Study 1 (students from sixth grade being slightly overrepresented in the self-determined cluster and underrepresented in the non-self-determined cluster; an opposite pattern was observed for students from ninth grade) and was significantly related to cluster membership in Study 2 (students from eighth grade being slightly overrepresented in the moderate cluster and underrepresented in the other clusters). These results are coherent with past literature in education that indicated a decrease of self-determined motivation as age increases (Otis, Grouzet, & Pelletier, 2005; Ratelle, Guay, Larose, & Senécal, 2004).

<sup>4</sup> An additional 3 (profile)  $\times$  3 (grade) ANOVA was conducted. It revealed (a) a significant effect of grade ( $p < .05$ ), the performance tended to be higher with the grade level; (b) a significant effect of the motivational profile ( $p < .01$ ), with a significant difference between the three profiles ( $p < .05$ ); and (c) no interaction effect ( $p = .28$ ).

Figure 2. Hypothesized model of achievement.

performance, and grade would be. More precisely, the best consequences were expected to be achieved by students displaying a self-determined profile, followed by students showing a moderate profile. Students with a non-self-determined profile were expected to show the lowest level of achievement. Our hypothesized model of achievement (see Figure 2) comprised three dependent variables. The effort exerted by the students was expected to be related to both their initial performance in the activity and to their motivational profile. Their final performance was expected to be related to their initial performance, their motivational profile, and their effort. In other words, for a similar initial performance in the activity, we expected that putting more effort and being more self-determined for the activity would result in higher improvement, and thus in a higher final performance. Finally, the grade obtained was hypothesized to depend not only on students' final performance, but also on initial and middle cycle variables, that is, their initial performance and motivation as well as the objective effort they exerted. Teachers, and particularly physical education teachers, have been shown to prefer hardworking students, whatever their level of ability (Biddle & Goudas, 1997; Covington & Omelich, 1979; Weiner, 1979). Moreover, teachers might take into account initial characteristics of their students (e.g., performance and motivation) to form expectations on their achievement, which may impact on the grade they give them at the end of the cycle (e.g., Jussim & Eccles, 1992; Trouilloud, Sarrazin, Martinek, & Guillet, 2002).

## Method

### Participants and Procedure

Two hundreds and fifteen students (99 girls, 116 boys) from a French high school volunteered to participate in the study. They were in seventh-grade ( $N = 115$ ), eighth-grade ( $N = 70$ ), and ninth-grade ( $N = 30$ ) classes. Their ages ranged between 10.5 and 16 years ( $M = 12.47$  years,  $SD = 1.05$ ), and all were involved in a gymnastics cycle. During the first lesson, students' motivation and their initial performance in the activity were assessed. Next, students' effort in gymnastics was measured in the middle of the cycle (i.e., between the fourth and sixth gymnastics courses). Finally, students' performance in gymnastics was appraised during the last class, and their grade was recorded.

### Measures

**Motivation.** The same scale as in Study 1 was used.

**Performance in gymnastics.** The assessment of students' performance in the activity at the beginning and at the end of the teaching cycle was identical to Study 1.

**Effort in gymnastics.** In the middle of the cycle, a videotape was used to evaluate the amount of effort provided by the students. The camcorder was placed in a fixed spot, in order to record the activity of the students when they worked on the stretched handstand back-drop task. Several students were involved in this workshop simultaneously, but there was enough space so that they could work at it at the same time. Furthermore, teachers were previously informed of the purpose of the camcorder and were asked not to interact with students completing this exercise. The number of repetitions of the exercise for 5 min was calculated and used as an indication of their investment in the activity.

**Grade.** After completion of the gymnastics cycle, all teachers provided the grades obtained by the students in gymnastics. French grades are scores comprised between 0 and 20, and the score of 10 is usually considered a mediocre result.

### Data Analysis

A confirmatory cluster analysis was conducted on the sample, taking the number of clusters emerging in Study 1 as a basis for the

Table 4  
Descriptive Statistics for the Three Clusters (Study 2)

Variable	<i>M</i>	<i>SD</i>	$\alpha$	Cluster 1 ( $N = 84$ ), self-determined		Cluster 2 ( $N = 91$ ), moderate		Cluster 3 ( $N = 40$ ), non- self-determined	
				<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>
1. IM toward stimulation	3.56	1.99	.88	5.67	1.03	3.09	1.11	1.71	0.80
2. IM toward knowledge or accomplishment	4.15	1.92	.84	5.65	1.14	3.98	1.13	1.94	0.90
3. Identified regulation	3.29	1.80	.80	5.13	1.29	3.22	1.07	2.06	1.08
4. Introjected regulation	3.24	1.60	.67	4.23	1.39	3.39	1.20	1.90	0.92
5. External regulation	3.51	1.71	.72	2.05	1.40	2.83	1.39	5.11	1.35
6. Amotivation	3.28	1.95	.88	1.77	1.30	2.80	1.31	5.94	1.14

analysis. Next, we tested the hypothesized model of achievement (see Figure 2) using path analysis.

### Results and Discussion

The means and standard deviations of the variables are shown in Table 4, as well as the alpha coefficients for multi-item variables and Bravais-Pearson correlations among all variables.

#### Confirmatory Cluster Analysis

A k-mean cluster analysis was conducted on the basis of the result of the hierarchical cluster analysis carried out in Study 1. This kind of analysis is considered confirmatory because it requires the researcher to provide a specific number of clusters expected to emerge in the sample. In line with the result obtained with the first sample, the fact that the second sample was comparable in terms of age and gender and that it originated from a school presenting relatively similar characteristics, the number specified in the cluster analysis was set at three. A MANOVA showed a significant multivariate main effect of cluster membership on motivational scores, Wilks's lambda = .12, Rao  $R(12, 420) = 64.66$ ,  $p < .01$ . Follow-up ANOVAs showed that cluster membership led to a significant effect on each motivational construct ( $ps < .001$ ,  $\eta^2 > .29$ ). Newman-Keuls post hoc analyses ( $p < .01$ ) revealed that the three groups were significantly distinct from each other on all motivational scales. The motivational profiles were similar to those observed with the hierarchical procedure in Study 1 (see Figure 3), with little change regarding the repartition of the students in the various clusters. The self-determined profile represented 39% of the sample ( $N = 84$ ), the moderate profile 42% ( $N = 91$ ), and the non-self-determined profile 19% ( $N = 40$ ). Students in the non-self-determined profile demonstrated higher scores for external regulation and amotivation than did those in Study 1. The clusters' size, as well as the means and standard deviations of their centroid, are shown in Table 4.

#### Motivational Profiles and Achievement Outcomes

The hypothesized model (see Figure 2) was tested with path analysis using Lisrel 8.54 (Jöreskog & Sörbom, 2003). Two contrasts were computed in order to compare the motivational profiles.

The use of contrasts is considered particularly appropriate in situations where specific hypotheses are formulated by the researcher concerning between groups differences on a dependent variable (Cohen, Cohen, West, & Aiken, 2003). We expected students with a self-determined profile to show the best level of achievement, followed by students with a moderate profile, and finally students with a non-self-determined profile. In order to compare students with a non-self-determined versus moderate profile, the weights used to compute the first contrast were  $-1, 0$ , and  $1$  for the non-self-determined, self-determined, and moderate profiles, respectively. The second contrast compared students with a moderate versus self-determined profile. The weights were  $-1, 0$ , and  $1$  for the moderate, non-self-determined, and self-determined profiles, respectively. A covariance matrix was used with the maximum likelihood estimation method. Because the model we tested was saturated, no adjustment fit indices are given. Only the weights of the paths as well as their level of significance are indicated in Figure 4.

The analysis revealed that final performance was predicted by the motivational profiles, controlling for initial performance ( $\beta = .62$ ). Students with a moderate profile obtained better performances than did those with a non-self-determined profile ( $\beta = .27$ ), and students with a self-determined profile obtained better performances than did those with a moderate profile ( $\beta = .30$ ).<sup>5</sup> The two contrasts and initial performance explained 52% of final performance's variance. On the other hand, students' final grade was predicted by their final performance ( $\beta = .44$ ), their objective effort ( $\beta = .13$ ), and their motivational profile, while controlling for their initial performance in gymnastics ( $\beta = .27$ ). More specifically, as was the case for final performance, students with a moderate profile obtained better grades than did those with a non-self-determined profile ( $\beta = .23$ ), and students with a self-determined profile obtained better grades than did those with a moderate profile ( $\beta = .25$ ). Altogether those variables explained 59% of students' grade variance. Objective effort was predicted by

<sup>5</sup> When a contrast shows a significant link with an outcome, it means that the two profiles differ significantly on this variable. If both of the contrasts show significant links, then the three profiles are distinct from each other, because if self-determined  $\neq$  moderate, and moderate  $\neq$  self-determined, then non-self-determined  $\neq$  self-determined.

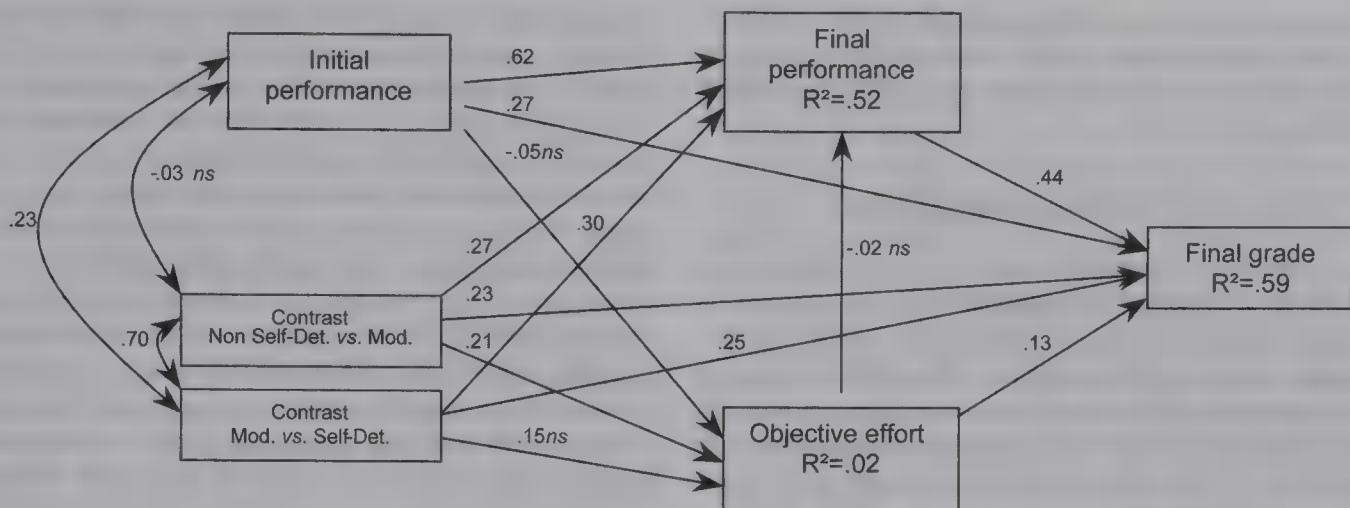

Figure 4. Path analysis contrasting the self-determined, moderate, and non-self-determined profiles (all paths are significant at  $p < .05$  except when specified by *ns*).

students' motivational profile while controlling for initial performance ( $\beta = -.05$ , *ns*). Students with a non-self-determined profile exerted more effort than did those with a non-self-determined profile ( $\beta = .21$ ), whereas there was no significant difference between students with a moderate or self-determined profile ( $\beta = .15$ , *ns*).<sup>6</sup>

Taken together, the analyses showed that students who showed a self-determined profile were those who achieved the most during the cycle: They provided more effort, realized the best final performance, and obtained better grades than did the students showing alternative profiles. By opposition, students who showed a non-self-determined profile were those who achieved less. A moderate motivational profile with average scores on all subscales was found to be linked to in-between achievement scores. One could assume that students showing this type of motivational profile are willing to provide effort in some certain circumstances, for example, if self-consciousness is salient. This might have been the case in this study, as the camcorder was visible, and thus some students may have tried to do the exercise just because this effort would be noticed. This could explain why no significant difference was observed between the moderate profile and the self-determined profile for this variable. However, this "superficial" effort does not seem sufficient to make progress, because there was actually a significant difference in terms of final performance between those two groups even after controlling for initial performance in the activity.

### General Discussion

Several authors have recently called on researchers to begin to pay attention to the possible ways to combine different types of motivation, and more specifically, the different types of motivation proposed by SDT (Fairchild et al., 2005; Vallerand, 1997). The purpose of this article was to adopt an original approach to examine students' motivation and the potential consequences that conceptualizing and regrouping different forms of motivation may have in education. More specifically, we chose to adopt a pattern-centered approach instead of testing specific effects of each motivational construct from SDT, or using an aggregated index of self-determination. That is, we examined how the different types of motivation combined into certain profiles and how those profiles were related to students' achievement. On one hand, recent

research has suggested that the Self-Determination Index may not be the only way to represent the different types of motivation proposed by SDT (e.g., Fairchild et al., 2005). On the other hand, looking at the separate effects of the different forms of motivation does not take into account the relationships between those motivations. Two prospective studies were conducted in a natural physical education setting in order to examine those issues.

### Description of the Motivational Profiles

Cluster analyses were conducted to examine which motivational profiles would emerge in our samples. Overall, the results confirmed those observed by Ntoumanis (2002) with British students, even if the procedure we adopted was not strictly identical. We observed two profiles with a clear motivational orientation toward either extremity of the theoretical continuum proposed by SDT (e.g., Deci & Ryan, 2000). These profiles provided support for the interactional hypothesis about the relations between motivational constructs (e.g., Vallerand & Fortier, 1998). The first cluster was oriented toward the self-determined part of the continuum of motivation, with high levels of IM and identified regulation, moderate levels of introjected regulation, and low levels of external regulation and amotivation. A second cluster was oriented toward the non-self-determined part of the continuum, with students scoring high on external regulation and amotivation, and low on other forms of motivation. The third motivational profile we observed presented average scores on each motivational variable. As proposed by some researchers (e.g., Lepper & Henderlong, 2000), it is possible that intrinsic and extrinsic forms of motivation combine in real-world settings. The results observed within our samples suggest that this can be the case if the level of those motivations remains moderate (see Figure 3). Compared with the results of Ntoumanis (2002), the repartition of the students in the clusters was rather similar for the moderate motivational profile, but fewer

<sup>6</sup> An additional model in which students' age was used as covariant revealed the same pattern of results and no significant association between this variable and the three objective criteria of students' achievement ( $\beta = .01$ ,  $p > .89$ ;  $\beta = -.06$ ,  $p > .25$ ;  $\beta = -.01$ ,  $p > .88$ , for effort, final performance, and final grade, respectively).

French students displayed a self-determined profile and more showed a non-self-determined profile. These differences can be explained by the fact physical education is compulsory for all high school students in France.

### *Motivational Profile and Achievement*

The second purpose of the studies was to examine the relations between motivational profiles and achievement in physical education. For both studies, we assessed achievement variables at different moments during the 10-week cycle. A longitudinal design is particularly appropriate because motivation is likely to have an impact on the variables of interest through time. Achievement was evaluated thanks to three objective criteria instead of the self-reported measures usually used in educational studies. First, we used a videotape to evaluate the effort exerted by the students during a task completion (Study 2). Second, we used the same procedure to assess students' initial performance in gymnastics (Study 2), as well as their performance 10 weeks later (Studies 1 and 2). Finally, the grade obtained for the class was provided by the teachers (Study 2).

A first hypothesis concerned the relationship between motivational profile at the beginning of the cycle and final performance in the activity at the end of the cycle. In Study 1, motivational profile was actually found to be significantly linked to students' final performance. The more that students displayed a self-determined profile of motivation, the higher was their performance. This positive link was previously observed in education (e.g., Miserandino, 1996), but with a cross-sectional design. The analyses conducted in Study 2 indicated that the students' motivational profile was significantly linked to their final performance, even after controlling for their initial performance. This is particularly important, because even if motivation was measured before performance in previous research, very little effort has been made to disentangle this effect from the effect of initial performance. Our result confirmed that no matter the initial level of skills of a student at the beginning of a teaching cycle, the more the student displayed a self-determined profile of motivation toward the activity, the higher would be his or her final performance.

We also examined the link between students' motivational profile and the effort they exerted. This link was significant when comparing the more self-determined students with the less self-determined ones. Students showing a moderate profile provided tangentially more effort than did students with a non-self-determined profile, but they were not distinguishable from students with a self-determined profile. Moderate levels of external regulation and amotivation combined with moderate levels of other motivations were thus found not to have too many negative consequences: It seems that this configuration is likely to promote effort in situations where self-consciousness is made salient, for example, when the performance is videotaped. A positive link was already observed in physical education between self-determined motivation and effort reported by the students themselves (e.g., Ntoumanis, 2001, 2002) or by their teacher (e.g., Standage et al., 2006). The pattern of result observed in our study confirmed this past literature but with a more objective measurement, because the effort of every student was evaluated with a videotape.

Finally, we examined the final grade obtained by the students. We expected that teachers' evaluations would first depend on the other indicators of achievement, namely the students' final perfor-

mance in the activity and the effort they exerted during the cycle. Indeed, teachers have been found to prefer more invested, hard-working students, whatever their level of performance (Covington & Omelich, 1979). This hypothesis was confirmed: Both indicators were significantly related to students' grades. It means that teachers gave better grades to students whom they perceived to work harder, even if they did not reach the greatest level of achievement. Motivational profile showed an indirect association with grade, thanks to its links with the effort provided and the final level of performance. Motivational profile was also found to have positive, direct links with the final grade given by the teacher, as well as the initial performance in the activity. This result suggests that teachers took into account some early characteristics of the students to evaluate them at the end of the cycle. One explanation of this result could be teachers' expectancies (e.g., Jussim & Eccles, 1992) and more precisely perceptual biases in their evaluation. This phenomenon is based on the influence teachers' early expectancies can have on their judgment of students' performance (e.g., Jussim & Eccles, 1995). Basically, if teachers have higher expectancies toward students who show a good performance at the beginning of the cycle, this could lead them to overevaluate their final level (see Trouilloud et al., 2002). Nevertheless, this hypothesis cannot be verified because teachers' variables were not measured in this study.

### *Implications for Self-Determination Theory and Research*

This work constitutes a substantial contribution to the SDT literature. Indeed, the representation of the multiple forms of motivation proposed by this theory represents one relatively unexamined issue to date. The motivational profiles observed in these studies and their links with students' achievement suggest interesting issues regarding the regulatory processes involved in education. The first issue to be addressed concerns the particularly negative pattern observed for students showing a non-self-determined profile. The association of high levels of external regulation and amotivation, associated with low level of every other form of motivation, was found to lead to poor effort, performance, and grade. A similar profile was previously observed by Ntoumanis and was associated with high levels of boredom and very low levels of enjoyment and effort (Ntoumanis, 2002). In the sport context, negative independent effects of the degree of external regulation and amotivation have been observed on short- and long-term persistence (Pelletier et al., 2001). The students displaying such motivational profiles are likely to "suffer from a lack of motivation and a sense of helplessness outside of the specific situations in which extrinsic rewards are available" (Lepper & Henderlong, 2000, p. 295). One might argue that, with the exception of when they are evaluated by their teacher, those students might have no motivation at all in class. They are likely to regularly adopt maladaptive strategies and avoid getting involved in the tasks proposed.

Our studies also underscore the particularly adaptive character of a motivational profile combining high scores of intrinsic motivation and identified regulation but also moderate levels of introjection and low levels of external regulation and amotivation. The importance of combining intrinsic and identified regulations was already underlined by Koestner and his colleagues (Burton et al., 2006; Koestner & Losier, 2002). They argued that possessing high levels of both types of regulation could allow one the flexi-

bility to adapt to a wide array of situations. More precisely, combining high levels of both intrinsic motivation and identified regulation is likely to lead to high levels of well-being and performance (Burton et al., 2006). More surprisingly, whereas it is considered a non-self-determined form of motivation, a moderate level of introjection was finally associated with the higher level of achievement. In spite of the negative affective states it implies, such as anxiety or guilt (Blais, Sabourin, Boucher, & Vallerand, 1990), this kind of regulation could likely enhance behavioral involvement. It was found to be related to persistence in previous work (Ntoumanis, 2002; Pelletier et al., 2001; Vallerand et al., 1997), but this relationship was observed only for a short-term period (e.g., Pelletier et al., 2001). The period of our studies was also relatively brief because of the 10-week teaching cycles. It would be interesting to investigate the educational outcomes of motivational profiles in the long term in order to verify if this motivational configuration is beneficial for achievement during one or several educational years.

It is important to note that a moderate level of introjection in itself does not guarantee those beneficial impacts on achievement. Indeed, students showing similar levels of introjection, associated with moderate levels of other kinds of regulation (i.e., what we labeled moderate motivational profile), did not show identical levels of performance in gymnastics, and they obtained lower grades. This result suggests that a moderate feeling of guilt or shame, as shown by the student motivated by introjection, does not necessarily have negative consequences, if at the same time the student gets a certain satisfaction from the activity (i.e., intrinsic motivation) and anticipates that the activity would help him or her to reach personal goals (i.e., identified regulation). Conversely, when these feelings are not associated with interest or personal value for the activity, the outcomes could be less positive.

Globally our results suggest an adaptive role of the self-determined motivational profile, as shown by students with high levels of intrinsic motivation toward stimulation, accomplishment, and knowledge; high levels of identified regulation; and also moderately high levels of introjection. These elements underscore the importance of the internalization process, thanks to which individuals do not act without feelings of control or competence and without reacting to external contingencies, that is, they do not show amotivation or external regulation. This result is coherent with the propositions of Koestner and Losier (2002), who assumed that it is appropriate to develop both intrinsic and identified goals. This "dual motivational system" would promote the pursuit of both short-term goals, thanks to "the energizing emotions such as interest and excitement" that it implies, and the pursuit of long-term goals that identification is more likely to enhance, because it gives "significance [to] one's current pursuits and fosters positive emotions such as pride in one's accomplishments in the domain" (p. 115).

Past research conducted in education has examined how the social context and more particularly how teachers could influence the degree of satisfaction of students' basic needs and motivations, depending on the motivational climate they generate. The teachers who support autonomy are more likely to generate the internalization of the activity among students. They spend more time listening to their students and acknowledge their perspective, they provide more support for the quality of students' performance and progress, and they promote more choice and initiative and participation in decisions (Grolnick & Ryan, 1989). In contrast, teachers

who are controlling use more directives; give more solutions to the students; criticize them more; and put more pressure on them using rewards, threats, and deadlines. There is empirical evidence showing that the degree to which teachers are autonomy supportive versus controlling is significantly linked with students' need satisfaction and motivations (see Reeve, 2002, for a review), especially in physical education (e.g., Ntoumanis, 2001; Standage et al., 2003).

Finally, Koestner and Losier (2002) also recommend providing a structure to promote self-determined forms of motivation where students have at their disposal consistent guidelines, rules, and expectations relative to their behavior and a rationale for the tasks and activities proposed. These authors also advanced that both autonomy support and structure are needed to lead to the internalization of the activity. Even if the educational climate was not taken into account in the present study, past literature has suggested that a teacher showing characteristics of an autonomy supportive climate and providing structure to the students would contribute to the development of a self-determined motivational profile beneficial for achievement.

### *Limitations and Research Perspectives*

These studies are not exempted from a certain number of limitations. First, the validity of the effort measure can be questioned, since the camcorder was visible. It is thus possible that a social desirability phenomenon occurred, leading some students to put more effort in the task than they usually did. Perhaps this can account for the low percentage of variance of this variable explained by the motivational profile, as well as the absence of significance for the path between effort and final performance. Second, the length of the cycle was relatively short, and the effects of motivation observed in 10-week cycles would probably be more important in studies carried out during a whole school year or with a follow-up of students over several years. Indeed, if students practice the same activities each year, the beneficial or detrimental effect of motivational profiles on achievement could be cumulative and lead to greater disparities between students at the end of high school, even if they had the same performance at the beginning. Moreover, the generalization of these results can be questioned, and further studies could replicate those findings in other activities or educational disciplines. Finally, as in many naturalistic studies, we cannot exclude that some of the relationships observed are due to the omission of a relevant variable (see, e.g., Judd & McClelland, 1989). For instance, the educational climate provided by the teacher might have had an impact on students' motivation and achievement at the same time. However, given that students' motivation was assessed during the first lesson of the cycle, the potential effect of the teacher climate is limited. Further studies should nevertheless control this variable.

# Teachers' Occupational Well-Being and Quality of Instruction: The Important Role of Self-Regulatory Patterns

Uta Klusmann, Mareike Kunter, Ulrich Trautwein, Oliver Lüdtke, and Jürgen Baumert  
Max Planck Institute for Human Development

Teachers' occupational well-being (level of emotional exhaustion and job satisfaction) and quality of instruction are two key aspects of research on teaching that have rarely been studied together. The role of occupational engagement and resilience as two important work-related self-regulatory dimensions that predict occupational well-being and teachers' instructional performance in the classroom was investigated. In Part 1 of the study, self-regulatory data from 1,789 German mathematics teachers were subjected to a latent profile analysis, yielding four self-regulatory types (healthy-ambitious, unambitious, excessively ambitious, and resigned) that differed significantly on emotional exhaustion and job satisfaction. In Part 2, the association between teachers' self-regulatory type and instructional performance was examined in a subsample of 318 teachers. Results showed that teachers' self-regulatory type predicted the quality of instruction in three of the four aspects of instructional performance examined. Moreover, teachers' self-regulatory type was systematically linked to differences in students' motivation. No association was found between teacher self-regulation and student achievement.

*Keywords:* teachers, instructional quality, emotional exhaustion, job satisfaction, latent profile analysis

High rates of early retirement among teachers and disappointing student outcomes in recent international educational assessments have fueled concerns that many teachers in Western industrialized countries are not succeeding fully in their work (Organisation for Economic Cooperation and Development [OECD], 2005; Vandenberghe & Huberman, 1999).

But what are "successful" (or "effective") teachers? What are the outcomes that successful teachers are expected to produce? Research on successful teachers can be classified into two main strands that rarely overlap. The first, research on learning and instruction, focuses on the quality of instruction as a major outcome variable that in turn predicts students' achievement gains and motivational and personality development (Bromme, 2001). The major emphasis is on the teacher's role as an instructor, and successful teachers are identified as those who provide good instruction. The second strand, research on occupational health,

focuses on teachers' health and affective well-being. In this research tradition, successful teachers are characterized as experiencing low stress, showing no symptoms of burnout, and reporting high job satisfaction (Kyriacou, 2001; Maslach & Leiter, 1999).

In the present article, we propose that these two core aspects cannot be separated and that research on successful teachers will profit considerably from taking both research traditions and sets of outcome measures into account. Specifically, we investigated whether differences in occupational well-being and instructional performance can be explained by teachers' self-regulatory patterns. Guided by a theory-based research model, we focused on the intraindividual interplay of two self-regulatory behaviors that are highly relevant in the occupational domain: work engagement and resilience (Hallberg & Schaufeli, 2006; Schaarschmidt, Kieschke, & Fischer, 1999). Based on the concept of balanced commitment (Hallsten, 1993) and conservation of resources theory (Hobfoll, 1989), we argue that a combination of high engagement in the teaching profession (work engagement) with the capacity to emotionally distance oneself from work and cope with failure (resilience) is associated with both high levels of occupational well-being (low levels of exhaustion, high job satisfaction) and better instructional performance, and in turn leads to favorable student outcomes.

There are two parts to our empirical study. In Part 1, we empirically identified different patterns of engagement and resilience by applying latent profile analysis to a sample of more than 1,700 German mathematics teachers. Moreover, we examined the relationship between these self-regulatory patterns and two measures of occupational well-being: emotional exhaustion and job satisfaction. In Part 2, drawing on a subsample of 318 teachers and their students, we explored differences in the instructional performance of teachers of the four different self-regulatory types and examined whether these differences are systematically associated with their students' achievement and motivational experience.

## Successful Teachers: Feeling Well and Performing Effectively in the Classroom

Our theoretical framework combines elements of the transactional perspective from health psychology (Lazarus & Folkman, 1987) with the extended process-product model and the expertise approach from research on learning and instruction (Bromme, 2001; Sternberg & Horvath, 1995). Features of the working environment and teachers' personal characteristics are conceived to be antecedents of teachers' occupational well-being, teachers' instructional performance in the classroom, and student outcomes (Maslach, Schaufeli, & Leiter, 2001; Shuell, 1996; Weinert & Helmke, 1995). Student achievement and motivational development are thus hypothesized to be affected by their experiences in the classroom, which are shaped by teachers' instructional performance. The relations proposed and variables considered are illustrated in Figure 1.

We do not examine the entire model in this article but focus instead on the relationship between selected teacher characteristics (i.e., profiles of self-regulatory behavior) and two aspects of success (i.e., teachers' occupational well-being and instructional quality). In the following sections, we first describe our conceptualizations of occupational well-being and instructional performance as criteria for successful teachers and then turn to the patterns of self-regulation that we consider crucial for obtaining these outcomes.

### Aspects of Teachers' Occupational Well-Being

Occupational well-being can be defined as the "positive evaluation of various aspects of one's job, including affective, motivational, behavioral, cognitive and psychosomatic dimensions" (Van Horn, Taris, Schaufeli, & Schreurs, 2004, p. 366). To date, research on teachers has tended to focus on the negative side of

well-being by exploring concepts such as stress, burnout, and low job satisfaction (Maslach et al., 2001; Schaufeli & Enzmann, 1998).

Kyriacou (2001, p. 28) defined teacher *stress* "as the experience by a teacher of unpleasant, negative emotions, such as anger, anxiety, tension, frustration or depression, resulting from some aspect of their work as a teacher." The experience of chronic stress is one of the core dimensions of burnout, a diagnosis that gained currency in the context of work-related strain in social workers. The classic and most popular definition of burnout was proposed by Maslach (Maslach, Jackson, & Leiter, 1996), who described it as a psychological syndrome characterized by three symptoms: emotional exhaustion, depersonalization, and reduced personal accomplishment. *Emotional exhaustion*, the most obvious manifestation and central quality of burnout, involves feelings of being emotionally drained and depleted of emotional resources. *Depersonalization* is characterized by a negative, callous, and detached attitude to others (in this case, students). *Reduced personal accomplishment* implies feelings of incompetence and a negative self-evaluation of job performance. In line with Rudow (1999) and Schaufeli and Enzman (1998), we regard burnout as a result of prolonged job stress. In the present study, we assessed the emotional exhaustion that teachers report with respect to their work, thus tapping a key dimension of burnout and a major operationalization of chronic stress.

In occupational research, the concept of *job satisfaction* is one of the most studied aspects of job-related well-being, reflecting "a positive (or negative) evaluative judgment one makes about one's job or job situation" (Weiss, 2002, p. 175), which can be explained by the perceived degree of need fulfillment within the organizational setting. The nature of the relationship between job satisfaction and stress is not yet clear: Whereas some researchers regard burnout as a cause for low job satisfaction, others assume the

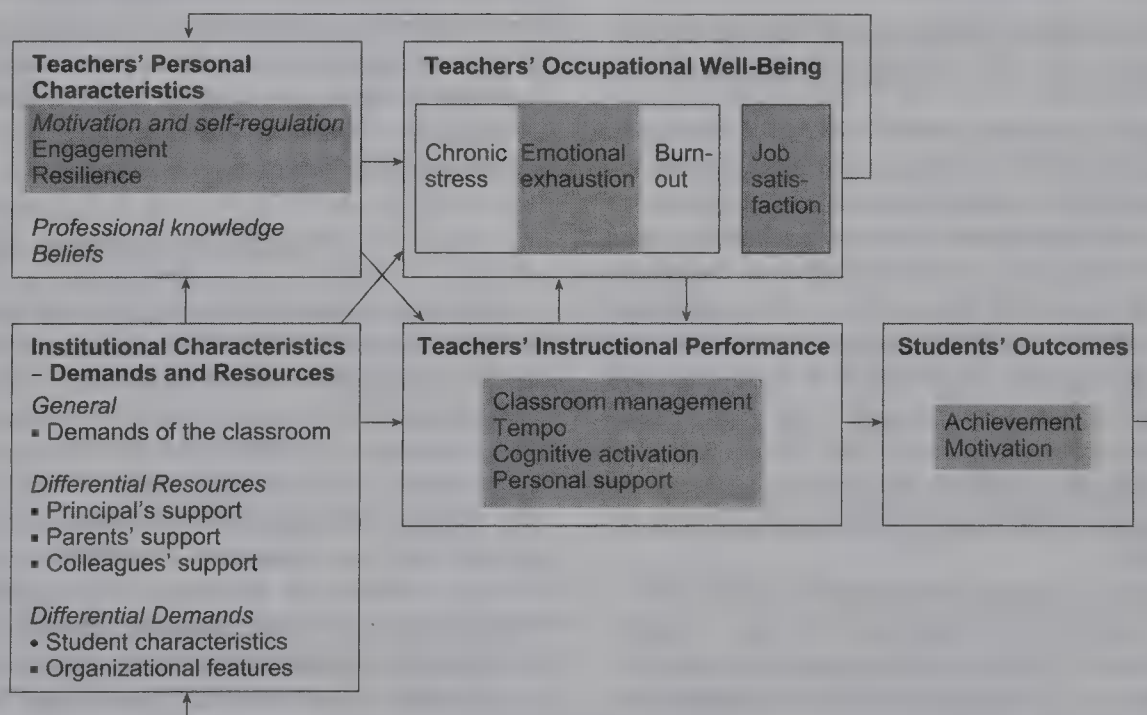

Figure 1. Heuristic working model of teacher characteristics, teachers' occupational well-being, and instructional performance. Only the shaded sections were examined.

opposite mechanism. Empirically, there is some evidence that low job satisfaction is a consequence of perceived stress at the workplace (Wolpin, Burke, & Greenglass, 1991).

Stress and job satisfaction reflect different aspects of teachers' occupational well-being (Van Horn et al., 2004). What they have in common is that their undesirable forms (i.e., high levels of stress and exhaustion and low levels of satisfaction) have negative consequences for individual psychological and physical health (Melamed, Shirom, Toker, Berliner, & Shapira, 2006) and for the organization itself in terms of lower performance and higher fluctuation (Judge, Thoresen, Bono, & Patton, 2001).

### *Teachers' Instructional Performance in the Classroom*

Teachers' main field of activity is the classroom. The crucial question is whether teachers succeed in creating challenging and adaptive learning situations and in effectively guiding their students through the learning process (Collins, Greeno, & Resnick, 2001)—in other words, whether their instructional behavior is successful.

Successful teachers can be described as performing well on at least four aspects of instructional behavior (see Kunter et al., 2007; Shuell, 1996). First, they succeed in establishing a well-structured environment characterized by low disturbance levels and efficient use of time (classroom management; Emmer & Stough, 2001). Second, they foster cognitive activation, enabling students to develop new insights and understandings (Turner et al., 1998). Third, successful teachers proceed at an appropriate pace that neither overtaxes nor underestimates students. Fourth, successful teachers are able to create a supportive social environment (e.g., show patience with students' mistakes, take time to talk about interpersonal problems, and behave fairly in critical situations) in which students receive personal guidance and feel personally valued (e.g., Ryan & Powelson, 1991). All four aspects of instructional quality are thought to be related to students' learning outcomes.

### *Personal Characteristics Contributing to Success in the Teaching Profession: Engagement and Resilience*

According to our theoretical framework, successful teachers are those who experience high levels of occupational well-being and succeed in creating optimal learning environments for their students. Several teacher characteristics have been proposed as being conducive to these outcomes. Research on health-related outcomes has focused on broad personality characteristics, such as emotional stability, internal locus of control, hardiness, self-efficacy, and coping styles (for an overview, see Schaufeli & Enzmann, 1998; Semmer, 1996). At the same time, research on instructional performance and student achievement has focused on cognitive characteristics, such as teachers' professional knowledge, beliefs, and self-efficacy (Shulman, 1986; Staub & Stern, 2002; Tschannen-Moran & Hoy, 2001).

We hypothesized two work-related personal characteristics to foster an effective approach to occupational demands: work engagement and resilience. Previous studies have shown both constructs to be important in teaching as well as in other professions. Work engagement is the willingness to invest energy and resources in one's job and is described as a "positive, fulfilling work-related state of mind" (Hallberg & Schaufeli, 2006), with high levels of

vigor (energy, effort) and dedication (in terms of inspiration, pride, and a sense of significance). High work engagement is associated with the willingness to stay in a particular organization and with high performance levels (Hakanen, Bakker, & Schaufeli, 2006). Resilience reflects the individual's reaction to work-related demands and describes the ability to deal with failure and to maintain a healthy distance with one's work (Schaarschmidt et al., 1999). It includes emotional distancing, a low tendency to give up after failure, active coping, and mental stability. Kyriacou (2001) described it as an active and palliative coping style.

Research on occupational behavior suggests that the most adaptive self-regulatory pattern is characterized by high levels of both engagement and resilience. In his theory of balanced commitment, Hallsten (1993) described individuals who show low vulnerability to stress as being able to distance themselves from their work and, at the same time, are highly engaged and committed. Similarly, conservation of resources theory (Hobfoll, 1989) states that well-being arises from a balance between the processes of investing resources (engagement) and recovering resources (resilience). Empirical evidence in support of this claim was reported by Schaar-schmidt et al. (1999), who used a cluster-analytic procedure to identify four different patterns of self-regulation in teachers. The healthy-ambitious (H) type, with high scores on both occupational engagement and resilience, is seen as the best adapted pattern. The unambitious (U) type is characterized by low occupational engagement but high resilience. The remaining two types are thought to be at high risk for burnout and stress. The excessively ambitious (A) type, scoring high on engagement and low on resilience, is characterized by excessive engagement, striving for perfection, and an inability to recover emotionally from work. The resigned (R) type is characterized by low engagement and low stress resistance.

Schaarschmidt et al. (1999) found that individuals of the H type reported less physical and psychological strain, had lower absence rates, and had lower means on the three burnout symptoms than the two at-risk types, with at-risk R type faring worse than at-risk A type. Moreover, teachers of the four self-regulatory types differed in their self-reported occupational knowledge and performance. Teachers of the H type ascribed to themselves more content and pedagogical knowledge than did teachers of the other self-regulatory types.

### *The Present Investigation*

In the present investigation, we focused on the intraindividual interplay of work engagement and resilience as teacher characteristics hypothesized to affect teachers' occupational well-being and instructional performance. Based on earlier studies, and in line with conservation of resources theory and the concept of balanced commitment (Hallsten, 1993; Hobfoll, 1989), we expected to find four different self-regulatory types. Moreover, we expected teachers who are both engaged and resilient to score highest on the outcome measures of well-being and instructional performance. We assumed that these teachers invest resources in their work and find meaning in their profession, but are at the same time able to distance themselves emotionally and to cope with failure. Beyond this H type, we expected the other three types to show distinct patterns of results on the outcome measures. In particular, engagement was expected to be more strongly associated with instruc-

tional performance than with well-being. In contrast, teachers scoring high on resilience (i.e., who are better able to distance themselves from work and to adopt an active coping style that protects them against exogenous stressors) were expected to score higher on measures of well-being.

We tested our assumptions in two sets of analyses. First, we empirically explored the four different patterns of self-regulation and related them to occupational well-being. Second, we examined how teachers' engagement and resilience are related to instructional quality and to students' motivational and achievement outcomes.

### Part 1: Four Profiles of Self-Regulatory Behavior and Their Association With Occupational Well-Being

In Part 1 of our study, we first investigated whether it is possible to empirically identify the four patterns of self-regulatory behavior described earlier (H, U, A, and R). To this end, we used latent profile analysis to categorize individuals into subgroups on the basis of the patterns of associations among variables indicating engagement and resilience. The model-based statistical approach of latent profile analysis compares favorably with the more widely used cluster-analytical approach in that it provides indices of the fit of any model tested, making it possible to compare models with different numbers of clusters (Vermunt & Magidson, 2002).

Second, we investigated whether these four teacher types differed in terms of emotional exhaustion and job satisfaction. Our four hypotheses were as follows: First, we expected teachers scoring high on both resilience and engagement (H type) to report the highest levels of job satisfaction and lowest levels of stress. Second, we expected teachers scoring high on resilience and low on engagement (U type) to report lower job satisfaction and more emotional exhaustion than H-type teachers. Although they are highly distanced from their work, these teachers may find no real meaning in their job. At the same time, given their high resilience scores, U-type teachers were expected to be more satisfied and less emotionally exhausted than the A-type and the R-type teachers. Third, we expected teachers of the A type, who are characterized by high engagement and low resilience, to show low job satisfaction and high emotional exhaustion. According to the principles of Hobfoll's (1989) conservation of resources theory, these teachers can be seen as trapped in a "loss spiral," investing a great deal of energy without experiencing sufficient gratification. Fourth, teachers with a profile of low engagement and resilience (R type) were expected to score lowest on job satisfaction and highest on emotional exhaustion. These individuals seem to have few resources to help them deal with work-related demands, resulting in exhaustion and dissatisfaction.

### Method

#### Sample

Data for the present research were provided by the Professional Competence of Teachers, Cognitively Activating Instruction, and the Development of Students' Mathematical Literacy study (COACTIV), which was embedded in the German extension to the 2003 cycle of the OECD's Programme for International Student Assessment (PISA). Within the German 2003 PISA assessment,

197 schools were drawn to form a representative sample of ninth-grade students. COACTIV surveyed up to 12 mathematics and science teachers in each of these schools, with teacher questionnaires being administered to assess biographical data, self-regulation, and occupational well-being. We received 1,789 completed questionnaires from the 1,940 teachers approached. On average, 9 teachers per school participated (range: 2–12 teachers). These teachers (47.8% male; age range: 25–65 years,  $M = 47.3$ ,  $SD = 9.4$ ) formed the basis for Part 1 of our study. The length of teaching experience ranged from 1 to 44 years ( $M = 20.6$ ,  $SD = 10.6$ ). All of the German secondary school tracks were represented.<sup>1</sup>

### Measures

**Engagement and resilience.** The work engagement and resilience dimensions were measured using eight scales from the Occupational Stress and Coping Inventory (AVEM; Schaar-schmidt et al., 1999). Means, standard deviations, and internal consistencies of the scale scores are provided in Table 1. Prompted by the instruction "We would like you to describe some of your typical behaviors, attitudes, and habits with respect to your working life," teachers were asked to rate their agreement with each item (four items per scale) on a 5-point response scale (1 = *strongly disagree*, 2 = *disagree*, 3 = *partly agree*, 4 = *agree*, 5 = *strongly agree*). *Work engagement* was tapped by the following subscales: subjective significance of work, career ambitions, exertion, and perfectionism. *Resilience* was assessed by the subscales emotional distancing, low tendency to give up after failure, active coping, and mental stability. As shown in Table 1, all scale scores demonstrated good to high internal consistency ( $\alpha$  ranged from .79 to .82).

**Emotional exhaustion.** Emotional exhaustion was measured by an established German adaptation (Enzmann & Kleiber, 1989) of the Maslach Burnout Inventory (Maslach et al., 1996). Participants were asked to rate their agreement with five statements (e.g., "I often feel exhausted at school") on a 4-point response scale (1 = *strongly disagree*, 4 = *strongly agree*). Internal consistency of the scale scores was good ( $\alpha = .80$ ).

**Job satisfaction.** We used a short German version (Merz, 1979) of the Work Satisfaction Scale of the Job Diagnostic Survey (Hackman & Oldham, 1975) to assess job satisfaction. This measure focuses on global satisfaction with work rather than on certain facets of the job (e.g., "Given the choice, I would definitely become a teacher again"). Teachers rated six items on a 4-point response scale (1 = *strongly disagree*, 4 = *strongly agree*). The scale score showed high internal consistency ( $\alpha = .84$ ).

### Statistical Analysis

Latent profile analysis is the procedure best suited to our aim of identifying qualitatively distinct self-regulatory patterns (Lubke &

<sup>1</sup> The German secondary school system comprises several tracks that differ in terms of student achievement levels, years of schooling, and the academic opportunities available after graduation. A broad distinction can be drawn between the academic track (Gymnasium) and the nonacademic tracks (e.g., Realschule, Hauptschule), in that the final Gymnasium qualification (the *Abitur*) is obligatory for university entrance. In the present sample, 30.4% of the schools belong to the academic track.

Table 1  
*Descriptive Results for the Self-Regulatory, Emotional Exhaustion, and Job Satisfaction Scales*

Scale	N <sub>1</sub>			N <sub>2</sub>			N items
	M	SD	α	M	SD	α	
Work engagement (scale range: 1–5)							
Significance of work	2.57	0.79	.82	2.55	0.78	.81	4
Career ambitions	2.79	0.78	.81	2.80	0.80	.82	4
Exertion	2.96	0.79	.79	2.96	0.80	.82	4
Perfectionism	3.45	0.72	.79	3.42	0.65	.73	4

Emotional exhaustion (scale range: 1–4)	2.10	0.62	.84	2.13	0.62	.82	5
Job satisfaction (scale range: 1–4)	2.95	0.71	.84	2.92	0.71	.84	6

Note. N<sub>1</sub> = 1,789; N<sub>2</sub> = 318.

Muthén, 2005; see Pastor, Barron, Miller, & Davis, 2007, for a didactical application). As a particular kind of mixture model, latent profile analysis can be applied to data that are assumed to consist of unobservable subgroups of individuals with different probability distributions. Although cluster analysis techniques are commonly used to divide persons into homogeneous subgroups, latent profile analysis offers several advantages over the traditional approach (see Pastor et al., 2007). Whereas cluster analysis is an exploratory technique, latent profile analysis is a model-based procedure that allows for more flexible model specification. In fact, it has been suggested that traditional cluster analysis is equivalent to a very restricted specification of a latent profile model (Vermunt & Magidson, 2002). Moreover, the fit indices provided in latent profile analysis enable different models to be compared and informed decisions to be made regarding the number of underlying classes.

The key difference between latent profile analysis and the common factor model is that “the common factor model decomposes the covariances to highlight relationships among the variables, whereas the latent profile model decomposes the covariances to highlight relationships among individuals” (Bauer & Curran, 2004, p. 6). In other words, factor models cluster items, whereas latent profile analyses cluster individuals (Lubke & Muthén, 2005). Because we were interested in patterns of self-regulatory behavior among teachers, we chose latent profile analysis to identify latent clusters of teachers.

We used three criteria to identify the number of latent clusters. First, we applied the Lo–Mendell–Rubin likelihood ratio test (LMR test; Lo, Mendell, & Rubin, 2001). This test compares the improvement in fit between neighboring class models (i.e., comparing the *k*-1 and *k*-cluster models) and provides a *p* value that can be used to determine whether there is statistically significant improvement in fit when an additional class is included (for applications, see Lubke & Muthén, 2005). Second, we evaluated the different cluster solutions in terms of their interpretability (mean patterns of clusters, differentiation of profiles, sizes of clusters). Third, we considered three commonly used information criterion indices based on the log likelihood of a fitted model and a penalty term for the number of model parameters and/or sample

size. Akaike’s information criterion (AIC) and Bayes’s information criterion (BIC) balance the improvement in fit associated with adding classes to the model against the number of parameters in the model. A decrease in these indices when an additional cluster is added indicates an improvement in model fit. Lubke and Muthén (2005) have proposed an adjusted BIC (aBIC), which applies a different penalty term in the equation for sample size.

All latent profile analyses reported in the present article were conducted using Mplus, Version 3 (Muthén & Muthén, 1998–2004).

Results

Identifying Different Self-Regulatory Styles

Latent profile analysis was conducted using the means of the eight scales assessing occupational engagement and resilience. Five models were specified, starting with a one-class model that estimated 16 parameters (8 variances and 8 intercepts). For each additional latent class, 17 new parameters were estimated (8 variances, 8 intercepts, and 1 class probability parameter). Table 2 presents the fit indices for the five latent profile models. Whereas the information criteria (AIC, BIC, and aBIC) decreased when additional latent classes were added, the LMR test provided clear support for the expected four-class solution. Because Lubke and Muthén (2005) suggested that content-oriented criteria be taken into account when specifying the number of latent classes, we inspected the mean patterns of the different solutions. The *z* scores of the eight scales assessing engagement and resilience (Figure 2) supported a four-class solution.

Class 1, which corresponded to the pattern of the H type (29.2% of participating teachers), was characterized by high scores on both the engagement and the resilience subscales (relative to the mean of the total sample). Class 2 conformed to the expected profile of the U type (25.4%) and was characterized by very low scores on the engagement scales and high scores on the four resilience scales. The third class, representing the A type (16.4%), was characterized by very high scores (more than one standard deviation above the overall group mean) on the engagement scales and

Table 2

*Fit Indices for Different Class Solutions: Latent Profile Analysis for the Class-Dependent Variance Model*

Model	No. of parameters	AIC	BIC	Sample-adjusted BIC	<i>p</i> LMR
1-class	16	32176.67	32264.50	32213.67	—
2-class	33	30338.93	30520.08	30415.24	.00
3-class	50	29666.28	29940.75	29781.90	.02
4-class	67	29184.12	29551.91	29339.05	.03
5-class	84	28911.41	29372.53	29105.66	.72

*Note.*  $N = 1,789$ . The 4-class solution was chosen for the subsequent analyses on the basis of the fit indices and profiles of the means. AIC = Akaike's information criterion; BIC = Bayes's information criterion; *p* LMR = Lo-Mendell-Rubin likelihood ratio test for  $n$  versus  $n - 1$  classes.

low resilience scores. Finally, the pattern of results for the fourth class conformed to the profile expected for the R type (29.0%), with low scores on both engagement and resilience.

We next explored whether there were any differences in gender, school track, age, and years of teaching experience among individuals assigned to the different types. Chi-square tests revealed differences in the gender distribution of the four types,  $\chi^2(3, N = 1,740) = 45.74, p < .05$ . In terms of effect sizes (Grissom & Kim, 2005), the gender differences among the four patterns can be seen as small ( $r = .16$ ), with a higher frequency of women in the R (34.9% of women vs. 22.8% of men) and A (18.3% of women vs. 14.7% of men) types, and a higher frequency of men in the U (29.7% of men vs. 20.9% of women) and H (32.7% of men vs. 25.9% of women) types. Further, we found differences in the frequency of academic- and non-academic-track teachers assigned to the four self-regulatory patterns,  $\chi^2(3, N = 1,779) = 11.44, p < .05$ . In terms of effect sizes, these differences can be seen as rather small ( $r = .08$ ), with a higher frequency of academic-track teachers in the A type (20.6% of academic-track teachers vs. 14.5% of

non-academic-track teachers) and a higher frequency of non-academic-track teachers in the R type (30.3% of non-academic-track teachers vs. 26.0% of academic-track teachers). Analysis of variance revealed a statistically significant but rather small overall effect for age,  $F(3, 1693) = 2.82, p < .05, \eta^2 = .005$ . A post hoc analysis (Student-Newman-Keuls) did not find statistically significant differences between any of the four groups, however. Similarly, there was no overall effect for years of teaching experience,  $F(3, 1698) = 1.96, p > .05, \eta^2 = .003$ .

#### *Self-Regulatory Styles and Their Association With Emotional Exhaustion and Job Satisfaction*

Did individuals of the four self-regulatory types differ in terms of the level of occupational well-being they reported? The correlational associations between the self-regulatory scales and the two well-being measures are reported above the diagonal in Table 3.

Figure 2. Z scores for subscales of engagement and resilience by self-regulatory type. H = healthy-ambitious type; U = unambitious type; A = excessively ambitious type; R = resigned type.

Table 3  
*Intercorrelations Between Self-Regulatory Dimensions (1–8), Teachers' Occupational Well-Being (9–10), Instructional Performance (11–14), and Student Outcomes (15–16)*

Note. Above the diagonal:  $N = 1,789$ ; below the diagonal:  $N = 318$ .

\*\*  $p < .01$ .

We performed analyses of variance (ANOVA) with post hoc tests (Student–Newman–Keuls) and analyses of variance and covariance (ANCOVA) to compare mean emotional exhaustion and job satisfaction across the four groups. A Bonferroni-type adjustment was made to avoid inflated Type I error through multiple testing. With a familywise error rate ( $\alpha$ ) of .05 and four significance tests (two ANOVAs and two ANCOVAs), the critical value for each test ( $\alpha$ ) was adjusted to .0125. The ANOVA (see Table 4) revealed substantial differences in the emotional exhaustion reported by the four groups,  $F(3, 1785) = 116.51, p < .001$ . At  $\eta^2 = .16$ , the effect size was large and indicated that the self-regulatory pattern accounted for about 16% of the variance in emotional exhaustion. As post hoc analyses (Student–Newman–Keuls) showed, teachers belonging to the H type reported statistically significantly less emotional exhaustion than teachers of the other types. On average, teachers of the U type reported more emotional exhaustion than the H type but less than the two at-risk types. As expected, the A type and the R type scored highest on emotional exhaustion, but they did not differ from each other. In terms of effect sizes, the difference between the average emotional exhaustion of the H type and both the R type (Cohen's  $d = 1.1$ ) and the A type (Cohen's  $d = 0.9$ ) can be classified as large. A large standardized difference was also observable between the U type and the R type (Cohen's  $d = 0.8$ ), and there was a medium-sized difference between the U type and the A type (Cohen's  $d = 0.6$ ). The average mean difference between the H and the U types can be considered small (Cohen's  $d = 0.3$ ; Henson, 2006).

Similar results were found for the job satisfaction of the four teacher types. Overall, we found substantial differences across the four types,  $F(3, 1785) = 59.19, p < .001$ . The moderate effect size ( $\eta^2 = .09$ ) indicated that about 9% of the variance in job satisfaction could be explained by the self-regulatory pattern. Post hoc analyses (Student–Newman–Keuls) showed that the H type scored highest on job satisfaction, followed by the U type. Teachers of the A and R types scored lowest and did not differ from each other. In terms of effect sizes, the difference between the average job satisfaction of the H type and both the R type (Cohen's  $d = 0.8$ ) and the A type (Cohen's  $d = 0.8$ ) was again considerable. A small mean difference was observed between the U type and the R type (Cohen's  $d = 0.4$ ), as well as between the U type and the A

type (Cohen's  $d = 0.4$ ), and between the H type and the U type (Cohen's  $d = 0.3$ ).

Because gender and school track (and age) were not equally distributed across the four types, we performed a further ANCOVA to control for any effects of these variables. Consistent with the homogeneity assumption in ANCOVA, the regression coefficients of the covariates were not found to be statistically significantly different across the different types. As shown in Table 4, the results of the ANCOVA confirmed the findings reported above, and the results remained stable.

### Summary Part 1

In Part 1 of our study, we used latent profile analysis to identify four different self-regulatory types. These empirically derived types were in line with our theoretical expectations of patterns of engagement and resilience. A combination of engagement and resilience was the most adaptive self-regulatory pattern in the school setting, as reflected in the levels of emotional exhaustion and job satisfaction reported. The H type scored more favorably on both well-being indicators, followed by the U type, which in turn differed statistically significantly from the A and R types. The latter two types did not differ statistically significantly from each other. We next investigated whether teachers' self-regulatory styles are also systematically linked to their instructional performance and to students' mathematics achievement and motivational experience in the mathematics classroom.

### Part 2: Resilience, Engagement, and Instructional Performance

Part 2 of our study extended previous research on teachers' instructional behavior in three respects. First, instead of relying on teacher self-reports, we drew on students' ratings of their teachers' instructional quality. Teachers' self-regulatory styles, emotional exhaustion, and job satisfaction are likely to color their perceptions of the quality of their teaching. In fact, a feeling of reduced personal accomplishment is a typical symptom of burnout; this relationship might lead to inflated associations between ratings of teaching quality and stress or emotional exhaustion when teacher

Table 4

*Mean Differences Between the Four Self-Regulatory Types on Emotional Exhaustion and Job Satisfaction: Results of Analysis of Variance (ANOVA) and Analysis of Covariance (ANCOVA)*

Scale	Self-regulatory types				ANOVA		ANCOVA	
	H N = 523	U N = 454	A N = 293	R N = 519	F (3, 1785)	$\eta^2$	F (3, 1785)	$\eta^2$

SD	0.59	0.69	0.78	0.70				

*Note.* Age, gender (dummy coded), and school track (dummy coded: 0 = non-academic tracks, 1 = academic track) were included as covariates in the ANCOVA. Means with different subscripts differ statistically significantly in the Student–Newman–Keuls post hoc tests. H = healthy-ambitious type; U = unambitious type; A = excessively ambitious type; R = resigned type.

\*  $p < .0125$ .

self-reports are the only data source. Second, in line with most recent educational research, we took a multidimensional perspective on teachers' classroom behavior. We considered several aspects of instructional quality, including classroom management, tempo, cognitive activation, and perceived social support. Third, we examined whether differences in the instructional performance of teachers are also reflected in students' motivational experience and achievement.

Our main hypothesis concerned differences in the instructional performance of the four teacher types. We expected the different self-regulatory patterns to become manifest in teachers' classroom behavior and therefore observable for students. Specifically, we expected teachers of the H type to show the highest quality of instruction. In contrast, teachers of the R type were not expected to have the necessary resources (in terms of motivational and self-regulatory abilities) to meet the challenges of the classroom and were expected to show particularly poor instructional performance. The highly engaged teachers of the A type were expected to do a much better job in the classroom. The instructional performance of teachers of the U type, who score high on resilience and low on engagement, was a matter of particular interest. Theoretically, they might be more able than their nonresilient counterparts to meet the challenges of the classroom, but it is questionable whether teachers who are not engaged in their profession provide high-quality instruction.

Are self-regulatory patterns also associated with student outcome variables, such as motivational experience and achievement? Provided that teachers of different self-regulatory styles showed the expected differences in instructional performance, we expected to find an association between teachers' self-regulatory types and students' motivational and emotional experience. Based on research on teacher motivation (Skinner & Belmont, 1993), we assumed that an optimal balance of teacher engagement and resilience (H type) would be positively related to students' motivational experience, mediated through teachers' instructional behavior. We further assumed that students taught by teachers of the A type, who were expected to show better performance ratings than teachers low on work engagement (U type and R type), would show higher motivation.

Although it has been established that students' achievement, particularly at the class level, is not easily influenced by short-term interventions and situational features (e.g., Prenzel, 2007), high levels of instructional quality might be expected to enhance student outcomes in the long run. In a more exploratory analysis, we therefore tested whether the four self-regulatory patterns were differentially linked to students' mathematics achievement.

## Method

### Sample

The database for Part 2 of the present study is a subsample of the 1,789 teachers surveyed in Part 1 and comprises those teachers who teach mathematics in each of the 387 ninth-grade classes sampled for PISA 2003 in Germany. The sample size was reduced to 318 from the theoretically possible 387 teachers/classes for several reasons (teachers not consenting to participate, the same teacher teaching more than one PISA class, teachers not completing all instruments, and exclusion of classes for which fewer than

10 student reports were available). Preliminary analyses showed that classes that provided a complete set of teacher and student reports did not differ from classes that did not in terms of school track, mean mathematics achievement, basic cognitive abilities, or mathematics motivation. The teachers' mean age (56.6% male) was 47.9 years ( $SD = 9.0$ ); their teaching experience ranged from 1 to 41 years ( $M = 22.56$ ,  $SD = 9.8$ ). Teachers and students in each class were administered questionnaires assessing teachers' personal characteristics and instructional performance and students' motivation, thus making it possible to link up teacher data with students' reports. Scores on the PISA student achievement tests could also be linked to the teacher data. On average, 12 students completed the questionnaires per teacher (range: 10–18).

To ensure comparability between the teacher sample used in Part 1 ( $N = 1,789$ ) and the subsample used in Part 2 ( $N = 318$ ), we tested whether the two samples differed in terms of age, emotional exhaustion, job satisfaction, the resilience and engagement scales, or the frequency of assignment to the four self-regulatory types. Except for a marginally significant difference in gender, with fewer female teachers in the Part 2 subsample than in the Part 1 sample, no significant differences were found.

### Classification of the Four Types

Our analysis of the subsample of 318 teachers considered in Part 2 was based on the self-regulatory styles to which they had been assigned in Part 1. The frequencies of the four types in the subsample were as follows: 28.6% H, 25.8% U, 15.4% A, and 30.1% R.

### Measures of Instructional Performance

Student ratings of their mathematics teacher's instructional behavior were assessed using a comprehensive instrument developed specifically for the COACTIV study (Kunter et al., 2007). For the purposes of the present study, we considered the teachers' behavior on the four key aspects outlined earlier: classroom management, tempo, cognitive activation, and perceived social support. Previous work has established the factorial validity of the subscales used to assess these four dimensions. We used eight subscales (with three to eight items each) and a 4-point response scale (1 = *disagree*, 4 = *agree*) to assess the four instructional aspects; each dimension was measured by two subscales that were averaged. These four dimensions can be reliably distinguished on the basis of students' ratings (Kunter & Baumert, 2006); moreover, they are associated with several external validation criteria.

As a means of obtaining a score for each teacher on each measure of instructional performance, individual student ratings were aggregated to produce a class mean. Because the following analyses focus on the class level, we first needed to assess the reliability of these aggregated student ratings. The intraclass correlations  $ICC_1$  and  $ICC_2$  are frequently used to determine whether aggregated individual-level ratings are reliable indicators of group-level constructs (Bliese, 2000; Lüdtke, Trautwein, Kunter, & Baumert, 2006). The  $ICC_1$  indicates the proportion of total variance in student ratings that is located between classes, reflecting systematic between-class differences in instructional ratings. The  $ICC_1$  can also be interpreted as an estimate of the reliability of a single student's rating: With growing differences between classes,

individual students' ratings provide increasingly accurate estimates of the class mean. In contrast, the  $ICC_2$  provides an estimate of the reliability of the class mean. It is calculated by applying a Spearman-Brown correction formula—based on the average number of students per class—to the  $ICC_1$ , taking into account the assumption that measurement error decreases with increasing numbers of raters. Class mean ratings can be considered reliable indicators at the class level if student ratings differ systematically between classes (as measured by the  $ICC_1$ ) and there are many raters per class (a fact that informs the  $ICC_2$ ).  $ICC_2$  values above .70 are considered to indicate that the assessment of the class-level construct is sufficiently reliable (Bliese, 2000).

**Classroom management.** This scale taps classroom *disturbance* (sample item: "Students mess around the whole time"; reverse coded; 3 items) and *inefficiency of time use* ("A lot of lesson time is wasted"; reverse coded; 3 items), as rated by students. Higher ratings reflect more efficient classroom management, with low levels of disturbance and efficient time use. The overall scale score can be seen as a reliable indicator of the class level ( $ICC_1 = .30$ ,  $ICC_2 = .84$ ;  $M = 2.46$ ,  $SD = 0.53$ ).

**Tempo.** Two subscales assessed whether the students perceived the pace of classroom interaction to be appropriate. The first subscale measured the perceived tempo of direct *interaction* with the teacher ("Our teacher does not leave us much time to think when asking questions"; 3 items); the second subscale assessed the general tempo of *instruction* ("We move on so quickly in lessons that a lot of students have difficulty keeping up"; 4 items). High scores on these subscales indicate that students perceive the instructional tempo to be too fast ( $ICC_1 = .22$ ,  $ICC_2 = .77$ ;  $M = 2.38$ ,  $SD = 0.38$ ).

**Cognitive activation.** This dimension describes the level of perceived challenge and cognitive autonomy provided by tasks and instruction (Stefanou, Perencevich, DiCintio, & Turner, 2004). Students rated the teacher's use of *cognitively activating tasks* (sample item: "Our teacher changes the setting of problems to find out whether we have really understood the mathematical idea"; 8 items) and the degree of perceived *cognitive autonomy* ("Our teacher lets us use our own strategies to solve difficult problems"; 8 items). Again, we used the mean score on both aspects in the further analyses ( $ICC_1 = .15$ ,  $ICC_2 = .68$ ;  $M = 2.78$ ,  $SD = 0.24$ ).

**Social support.** This social dimension of the teacher's instructional behavior was operationalized by two subscales: the students' perceptions of the teachers' *patience with students' mistakes* ("Our teacher is patient if someone makes a mistake in the lesson"; 3 items) and the teacher's perceived willingness to provide students with *personal support* ("Our teacher soon notices if a student has problems or worries"; 3 items). The mean score reliably assessed students' perceptions of teacher social support at the class level ( $ICC_1 = .30$ ,  $ICC_2 = .84$ ;  $M = 2.76$ ,  $SD = 0.44$ ).

### Assessment of Student Variables

**Students' motivational experience.** On the basis of the idea that positive motivational development depends on the degree to which the social context facilitates the satisfaction of intrinsic needs (Miserandino, 1996; Ryan & Powelson, 1991), we assessed students' perceived competence and autonomy during mathematics lessons as a measure of motivational experience. To this end, students rated perceived teacher support for their needs for autonomy and competence

on seven items from the Intrinsic Need Satisfaction in Class Scale (Kunter, Baumert, & Köller, 2007). All items (e.g., "In mathematics lessons I am considered capable of difficult tasks") were rated on a 4-point Likert scale (1 = *strongly disagree*, 4 = *strongly agree*). The overall scale score can be seen as a reliable indicator on the class level ( $ICC_1 = .13$ ,  $ICC_2 = .70$ ;  $M = 2.53$ ,  $SD = 0.59$ ).

**Students' mathematical achievement.** The international PISA 2003 mathematics assessment provided a measure of students' mathematical achievement. Parameters were estimated on the basis of item response theory scaling, resulting in weighted likelihood estimates ( $M = 0.0$ ,  $SD = 1.0$ ) of each student's mathematical achievement.

## Results

### Self-Regulatory Patterns and Instructional Performance

We expected to find that teachers' self-regulatory patterns were differentially related to their instructional performance, as rated by their students. Four regression analyses were conducted, with classroom management, interaction tempo, cognitive activation, and personal support, respectively, being regressed on teachers' self-regulatory patterns (see Table 5). The categorical variable self-regulatory type was dummy coded, and assignment to the R type was taken as the reference category. Hence, the regression coefficients of the self-regulatory types must be interpreted relative to teachers of the R type.

Results showed that none of the self-regulatory patterns statistically significantly predicted teachers' classroom management as reported by students. However, teachers of the H type scored statistically significantly lower on interaction tempo than teachers of the R type, indicating that their instructional pace was evaluated as being more appropriate to student needs. Neither the U type nor the A type differed statistically significantly from the R type in this respect. About 5% of the between-class variance in ratings of interaction tempo was accounted for by the teacher's self-regulatory pattern ( $R^2 = .05$ ); in terms of effect sizes, this association can be considered to be of small size.

Next, we examined students' reports on the level of cognitive activation provided in mathematics lessons and found statistically significant associations for the H type and the A type. Both the H type and the A type scored higher than the R type on this dimension, indicating that students in classes taught by teachers of the H or A type described their instruction and the tasks set as more cognitively demanding than students in classes taught by teachers of the R type. However, the amount of between-class variance in students' ratings of cognitive activation explained by teachers' self-regulatory patterns was rather small ( $R^2 = .02$ ).

In terms of the personal support the teachers provided, those of the H type again scored higher than teachers of the R type, indicating that engaged and resilient teachers were perceived to be more attentive to their students' individual needs. Teachers of the other two patterns did not differ statistically significantly from the R type. About 8% of the between-class variance in students' ratings of individual teacher support was explained by teacher type ( $R^2 = .08$ ).

Because gender and schools tracks were not equally distributed across the four types, we re-ran the regression analyses, controlling for these variables. As shown in Table 5, the pattern of results remained stable.

Table 5  
Self-Regulatory Types and Instructional Performance: Results of Multiple Regression Analysis

Type/variable	Instructional performance

Note. School track is dummy coded: 1 = academic track, 0 = non-academic tracks. Tempo: low scores indicate an adequate tempo. R (resigned type) is the reference category. M = model; H = healthy-ambitious type; U = unambitious type; A = excessively ambitious type.  
\*  $p < .05$ . \*\*  $p < .01$ .

Self-Regulatory Patterns and Student Outcomes

We further hypothesized that teachers' self-regulatory behaviors were associated with students' motivational experience and achievement. Students' motivational experience scores were regressed on teachers' self-regulatory types. The results (see Table 6) revealed a statistically significant association between the H type and students' motivational experience. Students taught by teachers of the H type reported more pronounced experiences of autonomy and competence than did students taught by teachers of the R type. However, the amount of variance explained in student motivation was small ( $R^2 = .02$ ). Again, the link between teachers' self-regulatory types and student motivation remained stable when we controlled for school track and teacher gender.

School track		−.25**		−.21**
R <sup>2</sup>	.02	.08	.51	.54

Note. School track is dummy coded: 1 = academic track, 0 = non-academic tracks. R (resigned type) is the reference category. M = model; H = healthy-ambitious type; U = unambitious type; A = excessively ambitious type.  
\*  $p < .05$ . \*\*  $p < .01$ .

In an additional step, we tested whether the association found between teachers' self-regulatory type and student motivation was mediated by instructional performance in the classroom, as suggested by our theoretical model. To this end, we used the methodological approach suggested by Baron and Kenny (1986). Following the baseline model (M), in which student motivation was predicted by teachers' self-regulation (see M<sub>1</sub>/M<sub>2</sub> in Table 6), we conducted a multiple regression analysis in which student motivation was regressed on both teachers' self-regulatory type and instructional performance. Because classroom management was not found to be associated with the self-regulatory type (see Table 5), it was not included in this analysis (M<sub>3</sub>). Results revealed that two of the three remaining instructional performance measures were indeed related to the outcome variable: Degree of cognitive activation and personal support provided by the teacher were both statistically significant predictors of students' motivational experience. The tempo of classroom interaction was not related to students' motivational experience. Most important, the association between the H type and students' motivational experience decreased from a significant standardized regression coefficient of .15 when entered by itself to a nonsignificant .02 when instructional performance was included in the regression, suggesting a complete mediation.

In order to investigate which of the two dimensions of instructional performance (cognitive activation vs. personal support) was responsible for the assumed mediation effect, we formally tested the significance of both indirect effects (MacKinnon, Fairchild, & Fritz, 2007), using the product of coefficients strategy, also known as the Sobel test (Baron & Kenny, 1986). Results revealed a significant indirect effect of the H teacher type on students' motivation via perceived personal support ( $z = 4.68, p < .05$ ), as well as an indirect effect via cognitive activation ( $z = 2.87, p > .05$ ), thus suggesting that the association between teachers' self-regulatory type and student motivation is mediated by students' perceptions of both personal support and cognitive activation.

Finally, mathematics achievement scores were regressed on teachers' self-regulatory type. Results showed that students' mathematics achievement on the class level was not related to the

teachers' self-regulatory patterns ( $R^2 = .002$ ), indicating that there was no direct link between teachers' self-regulation and their students' achievement.

### *Summary: Part 2*

In line with our hypotheses, the results revealed statistically significant differences between teachers of different types in student ratings of instructional tempo, cognitive activation, and personal support, with teachers of the H type receiving the most favorable student ratings relative to teachers of the R type. No clear differences were found between teachers of the other self-regulatory types. Teachers' self-regulatory type was also systematically linked to students' motivational experience in lessons, with classes taught by teachers of the H type feeling more competent and autonomous. Congruent with our theoretical framework, this association was mediated by personal support and by the cognitive activation provided by teachers of the H type. No systematic associations were found for students' mathematics achievement. In sum, teachers' self-regulatory styles seem to be an important factor in successful teaching.

### General Discussion

The present research was conducted to investigate how teachers' self-regulatory patterns in response to work-related demands relate to two indicators of their professional success, namely occupational well-being and instructional performance. Our results show that the self-regulatory dimensions of work engagement and resilience are highly relevant in explaining both outcomes. In this section, we discuss the implications of the four self-regulatory types for teachers' occupational well-being and its possible developmental trajectories, as well as for the educational process in terms of instructional performance and educational outcomes.

#### *Patterns of Teacher Self-Regulation: Implications for Occupational Well-Being*

The main objective of our research was to examine individual configurations of two self-regulatory dimensions. Based on conservation of resources theory (Hobfoll, 1989) and the concept of balanced commitment (Hallsten, 1993), we expected the most adaptive self-regulatory style to be characterized by the concurrence of work engagement and resilience. Indeed, teachers of the H type, who exhibited this kind of self-regulatory style, showed the most favorable results on both measures of occupational well-being: They had the lowest ratings on emotional exhaustion and the highest ratings on job satisfaction.

Besides these H-type teachers, we identified three other self-regulatory types, all of which reported lower occupational well-being than the H type. Teachers of the A type and the R type, in particular, can be considered "at risk" in terms of their occupational well-being and, in the long run, probably in terms of their health (Melamed et al., 2006). The outcomes of the R type, who scored lowest on both indicators of occupational well-being, were the least favorable. From the perspective of the conservation of resources theory, it seems reasonable to speculate that, even though teachers of the R type do not invest much energy in their work, their inability to distance themselves from their work prob-

ably poses a further threat to their other resources (e.g., personal resources such as self-esteem, locus of control), which might, in turn, lead to a further decrease in their engagement (Hobfoll & Freedy, 1993). Without intervention measures, it is likely that their well-being will decrease further over time.

Interestingly, although differing fundamentally from the R type in their self-regulatory style, teachers of the A type, who are characterized by high engagement and low resilience, showed similar levels of exhaustion and dissatisfaction as were shown by teachers of the R type. Conversation of resources theory suggests that the resources of teachers of this group are depleted by their excessive exertion (Hobfoll & Freedy, 1993). From an organizational perspective, this result can also be interpreted in the light of the effort-reward imbalance model (Siegrist, 1996), which explains low occupational well-being in terms of an imbalance of the effort exerted and the rewards experienced. Teachers of the A type reported high engagement but received relatively low student ratings (see Part 2 of our study), which may be interpreted as indicating a lack of reward.

Findings on the teachers assigned to the U type, who scored lowest on all engagement subscales but relatively high on resilience, are especially interesting from a motivational perspective. Teachers of this type scored only slightly lower than teachers of the H type on the well-being measures. They were, however, considerably less engaged in their work, which could put them "at risk" of failing to meet the demands of the teaching profession.

These results confirm our main assumption that the abilities to distance oneself emotionally from one's work and to cope with failure (which are high in both the H type and the U type) seem particularly important for teachers' occupational well-being. Given that teachers of the H type reported higher levels of well-being than teachers of the U type, our findings suggest that both resilience against work-related demands and engagement in the teaching profession are important factors in teachers' occupational well-being.

#### *Patterns of Teacher Self-Regulation: Implications for Teachers' Instructional Performance and Student Outcomes*

As shown in Part 2 of our study, teachers' self-regulatory patterns were important not only for their experience of occupational well-being, but also for their instructional performance. Our main hypothesis—that highly engaged and resilient teachers of the H type would outperform teachers of the other types—was confirmed. Indeed, teachers of the H type received the most favorable student ratings in almost all aspects of instructional performance. However, with one exception, the A type was not significantly more successful than the R type in terms of instructional performance. This finding suggests that there is no clear linear association between the engagement shown by a teacher and students' ratings of instructional performance and provides further support for the advantages of achieving a balance between engagement and resilience.

It is interesting that our findings revealed differential associations between the instructional features considered. The strongest effects were found for teachers' personal support and an adequate interaction tempo. A somewhat smaller effect was found for the amount of cognitive activation experienced by students. Classroom

management was the only dimension for which no differences were apparent across teachers of different self-regulatory types. It seems that teachers' ability to perform basic classroom management tasks, such as establishing order, is almost independent of their motivational orientation. Teachers with low engagement were quite able to establish "normal routine" in the classroom (Doyle, 1986), but only teachers of the H type had the capacity to respond adaptively to their students' needs, as reflected in student reports of personal support, interaction tempo, and cognitive activation.

As expected, teachers' self-regulatory patterns not only affected their instructional performance, but were also linked to students' motivational experience. Students in classes taught by engaged and resilient teachers reported more positive motivational experience in mathematics lessons than students in classes taught by any of the other teacher types. Because this effect is mediated by teachers' personal support and, to a lesser degree, by the perceived level of cognitive activation, this result emphasizes that these aspects of instructional performance are crucial for students' motivation. Teachers' self-regulatory patterns did not affect students' mathematics achievement, however. A possible explanation for this finding is that this association is a long-term one that may be mediated by students' motivation and is therefore unlikely to be found in a cross-sectional design. It is also possible that other teacher qualities, such as professional knowledge, have a stronger direct effect on students' achievement (Shulman, 1986). Moreover, the PISA 2003 assessment administered was not tailored to the German Grade 9 mathematics curriculum but instead to tested material covered in Grades 5 through 9. Although the test was implemented at the end of the school year, the current teacher's scope to influence achievement scores for the better was clearly limited.

### Limitations and Future Research

To our knowledge, this is the first study in the area of teacher research to consider how teachers' occupational well-being, students' ratings of instructional performance, and students' motivation and achievement relate to teachers' personal characteristics. At the same time, our study has at least two notable limitations. First, although we report data from a large sample embedded in a large-scale assessment, it remains unclear whether the results can be generalized beyond secondary-level mathematics teachers in Germany. Second, the cross-sectional design of the study does not allow causal inferences to be made between the variables investigated. As mentioned earlier, it would be interesting to investigate the development of self-regulatory processes, occupational well-being, and instructional performance, as well as students' motivational and achievement development over time. In particular, a closer examination of the interplay between—and causal direction of—student characteristics and behavior and teachers' performance would be of major interest (Maslach & Leiter, 1999). Researchers seeking to investigate how classroom experiences influence teachers' performance and occupational well-being need to bear in mind that one teacher interacts with several different classes per day, all of which would probably have to be included in a longitudinal study.

### Practical Implications

In addition to their theoretical relevance, our findings have practical implications, as reflected by the magnitudes of the effect sizes observed. First, teacher education and in-service training that include aspects of teachers' self-regulatory skills and coping behavior might enhance not only teachers' occupational well-being but also their instructional quality. Second, when problems become evident in teachers' occupational well-being or instructional performance, knowledge of the different self-regulatory types might facilitate individually tailored intervention strategies. Some teachers (e.g., the U type) might need more support with motivational aspects, whereas others (e.g., the A type) might benefit more from developing coping strategies to increase their levels of resilience against the potential stressors of the teaching profession.

Drawing on the work of L. S. Shulman (1986), the authors present a conceptualization of the pedagogical content knowledge and content knowledge of secondary-level mathematics teachers. They describe the theory-based construction of tests to assess these knowledge categories and the implementation of these tests in a sample of German mathematics teachers ( $N = 198$ ). Analyses investigate whether pedagogical content knowledge and content knowledge can be distinguished empirically, and whether the mean level of knowledge and the degree of connectedness between the two knowledge categories depends on mathematical expertise. Findings show that mathematics teachers with an in-depth mathematical training (i.e., teachers qualified to teach at the academic-track Gymnasium) outscore teachers from other school types on both knowledge categories and exhibit a higher degree of cognitive connectedness between the two knowledge categories.

**Keywords:** professional knowledge of mathematics teachers, pedagogical content knowledge, content knowledge, expert teachers

Imagine you are a mathematics teacher. A student puts his hand up and says: "I don't understand why  $-1$  times  $-1$  equals  $+1$ . I know it's the correct result, but it makes no sense to me. Why does multiplying two negative numbers give a positive number?" How would you explain this result to your student? Scenarios like these are typical for the task of teaching. In order to respond appropriately, teachers not only need to understand the mathematical concepts underlying the question, they also need to know how these concepts can best be explained to students.

The relevance of teachers' domain-specific knowledge to high-quality instruction has been discussed, particularly in the context of mathematics teaching (Ball, Lubienski, & Mewborn, 2001;

Fennema & Franke, 1992). Drawing mostly on qualitative data, it has been shown that a deep understanding of mathematical concepts may enable teachers to access a broad repertoire of strategies for explaining and representing mathematical content to their students (Ball, Hill, & Bass, 2005; Ma, 1999). First quantitative evidence shows that students' learning gains in mathematics may be predicted by their teachers' mathematics-related knowledge (Hill, Rowan, & Ball, 2005). The precise nature of teachers' knowledge (i.e., the content and structure of knowledge relating to specific school subjects) remains empirically uncertain, however. Following Shulman (1986, 1987), a theoretical distinction is often drawn between domain-specific subject-matter knowledge, content knowledge (CK), and the knowledge needed for teaching a specific subject, pedagogical content knowledge (PCK). These two knowledge categories may be hypothesized to represent conceptually distinct forms of knowledge, with the former perhaps being the prerequisite for the development of the latter. Alternatively, it is conceivable that the two are merged to form a single body of domain-specific knowledge for teaching (for first results on the knowledge of elementary teachers, see Hill, Schilling, & Ball, 2004, or Phelps & Schilling, 2004). Despite its great relevance to the development of teachers' knowledge and possible implications for teacher training curricula, this issue remains empirically unresolved, primarily because very few instruments are yet available to tap teachers' knowledge directly.

In this article, we present an empirical approach to assessing the knowledge of secondary-level mathematics teachers and investigate whether the theoretical distinction between pedagogical content knowledge and content knowledge can be verified empirically. We report on the theory-driven construction of a test to assess the

knowledge categories of PCK and CK directly, and on its application in a German teacher sample. Our investigation of commonalities and differences in CK and PCK was informed by the expertise research literature, which has repeatedly found that the knowledge base of experts is not only more extensive than that of novices, but also more connected and integrated (Chi, Feltovich, & Glaser, 1981; Schmidt & Boshuizen, 1992; Simon & Chase, 1973). We therefore investigated whether the association between PCK and CK varies according to the level of mathematical expertise, hypothesizing that the association between the two categories of knowledge will be substantially closer in teachers high in mathematical expertise, possibly even constituting one inseparable body of knowledge. We addressed this question by capitalizing on a quasi-experimental situation that is specific to teacher education in Germany. The amount (and depth) of content-specific instruction provided to teacher candidates varies substantially depending on whether or not they aspire to teach in the academic-track Gymnasium (GY). One group of teachers can therefore be identified as “mathematical content experts.”

### The Concepts of Pedagogical Content Knowledge and Content Knowledge

The distinction between teachers’ knowledge about teaching in a specific domain (PCK) and their domain-specific subject-matter knowledge (CK) has been widely embraced by the research community. The core meaning of pedagogical content knowledge is best represented by Shulman’s (1986, pp. 9–10) original definition, which states that pedagogical content knowledge includes knowledge on how best to represent and formulate the subject to make it comprehensible to others, as well as knowledge on students’ subject-specific conceptions and misconceptions (see also Grossman, 1990). Content knowledge, on the other hand, describes a teacher’s understanding of the structures of his or her domain. According to Shulman, “The teacher need not only understand *that* something is so, the teacher must further understand *why* it is so” (Shulman, 1986, p. 9), which implies that teachers’ content knowledge should represent a deep understanding of the material to be mastered by the students. Shulman’s definitions describe teachers’ pedagogical content knowledge and content knowledge in generic terms. However, domain-specific approaches have been found to provide more valuable, in-depth insights into instructional processes and their prerequisites (Mayer, 2004b).

### Mathematics Teachers’ Pedagogical Content Knowledge and Content Knowledge

Research has identified several aspects that are specifically important to successful mathematics instruction, and that might therefore be used to conceptualize pedagogical content knowledge in a mathematics-specific approach. Most importantly, tasks play a central role in mathematics instruction (Christiansen & Walther, 1986), accounting for much of the time allocated to mathematics lessons. Appropriately selected and implemented mathematical tasks lay the foundations for students’ construction of knowledge and represent powerful learning opportunities (de Corte, Greer, & Verschaffel, 1996; Williams, 2002). Knowledge about the potential of mathematical tasks for learning is thus a first important aspect of mathematical pedagogical content knowledge. Second,

teachers need to work with students’ existing conceptions and prior knowledge. Because errors and mistakes can provide valuable insights into the implicit knowledge of the problem solver (Matz, 1982), it is important for teachers to be aware of typical student misconceptions and comprehension difficulties. Students’ construction of knowledge often only succeeds with instructional support and guidance (Mayer, 2004a), which may entail various forms of explanations or the explicit use of representations. The knowledge of appropriate mathematics-specific instructional methods is thus a third important component of mathematical pedagogical content knowledge. Whereas the latter two components are based directly on Shulman’s (1986) generic conceptualization, we added the component of knowledge on tasks as a third, mathematics-specific component of mathematical pedagogical content knowledge.

The domain-specific conceptualization of teachers’ content knowledge seems straightforward. Clearly, teacher knowledge should go beyond an awareness of the material to be mastered by students; rather, teachers should possess mathematical background knowledge of the content covered in the school curriculum at a much deeper level of understanding than their students. This background knowledge of school curriculum content forms a knowledge base that is specific to teachers, in that it overlaps only partially with the mathematics typically taught at university.

### The Interplay Between Pedagogical Content Knowledge and Content Knowledge

Although the distinction between pedagogical content knowledge and content knowledge appears highly plausible at a theoretical level, its empirical basis is far from certain. Despite repeated calls for reliable and valid measurement assessments of teachers’ knowledge (e.g., Lanahan, Scotchmer, & McLaughlin, 2004), instruments suitable for assessing the categories of teachers’ knowledge remain scarce. To date, only a few studies have investigated PCK and CK empirically. In some of these studies, mathematics teachers’ content knowledge was not tested explicitly, because researchers did not want to give the impression of “testing” teachers (e.g., Kennedy, Ball, & McDiarmid, 1993). Other studies aiming to tap both knowledge categories found that, although it is possible to construct separate tests in principle, the overlap between the two categories was in fact so high that a global factor of knowledge relating to mathematics instruction seemed just as likely (Hill et al., 2004; Kahan, Cooper, & Betha, 2003). At the same time, a study with elementary teachers in the domain of reading found separate categories only, and no common factor (Phelps & Schilling, 2004). One explanation for these inconclusive results may be that the structure of knowledge differs across teacher populations. Studies comparing the knowledge base of experienced and novice teachers (for an overview see Berliner, 2001) suggest that expert teachers not only know more than novice teachers, but that their knowledge is differently structured and may be more highly integrated. This conclusion is in line with findings from expertise research in other domains, which show that experts’ knowledge bases are usually not only more extensive than those of novices, but also more connected and integrated (Chi et al., 1981; Schmidt & Boshuizen, 1992; Simon & Chase, 1973). Whether or not teachers’ pedagogical content knowledge and content knowledge are separable categories of knowledge may therefore be a

function of different levels of expertise. All previous empirical attempts to test models of teachers' knowledge have looked at elementary teachers, who can be assumed to have lower levels of subject-specific expertise. It thus seems worth examining the distinction between CK and PCK in a sample of secondary-level teachers.

### The Present Investigation

The goal of the present article was to construct and to establish a test of secondary mathematics teachers' PCK and CK and to use this test to examine the level and the connectedness of the two knowledge categories in two groups of teachers with different mathematical expertise. To specify our research hypotheses and make them empirically testable, we first clarified our approach to the concepts of *connectedness* and *mathematical expertise*.

Our methodological approach is based on a structural equation framework, in which PCK and CK are conceptualized as latent variables. The latent correlation between PCK and CK is particularly relevant to the issue of distinguishability (see Figure 1a). A higher latent correlation between PCK and CK indicates higher cognitive connectedness between the two knowledge categories. Moreover, a correlation close to one may indicate that the two knowledge constructs indeed form a single, indistinguishable body of knowledge on the cognitive level. In the PCK-CK model (Figure 1a), the means of the two knowledge constructs are depicted by paths from the triangle representing the mean structure to the two latent variables.

We used a quasi-experimental approach to examine whether higher connectedness is a function of higher expertise, attributing expert status on the basis of the teachers' university training (for an overview of alternative ways to identify expert teachers, see Palmer, Stough, Burdinski, & Gonzales, 2005). In Germany, all candidates entering a teacher training program must have graduated from the highest track in the school system, the GY, and received the Abitur qualification. At university, those aspiring to teach at the secondary level must choose between separate degree programs qualifying them to teach either at GY or in the other secondary tracks (e.g., Realschule or Sekundarschule). GY and non-Gymnasium (NGY) teacher education students are usually strictly separated during their university training. One of the main differences in their degree programs is the subject matter covered: Students training to teach at GY cover an in-depth curriculum comparable to that of a master's degree. Relative to their colleagues, who receive less subject-matter training (and usually spend less time at university), GY teachers may therefore be considered mathematical experts, and the two groups of teachers may be contrasted in a quasi-experimental approach. Given that previous studies (e.g., Hill et al., 2004) have presented evidence for a close connection between the two subject-specific knowledge categories, and because CK is often discussed as a prerequisite for PCK, we expected GY teachers would score higher in the PCK test as well, although the difference would probably not be as pronounced as for the CK test.

On the basis of this conceptualization of connectedness and mathematical expertise, we formulated our research hypotheses as follows:

*Hypothesis 1:* GY teachers significantly outscore their colleagues from NGY school types on CK and PCK.

*Hypothesis 2:* The latent correlation between PCK and CK is substantially higher for GY teachers than for NGY teachers (perhaps even approaching  $r = 1$ ).

### Method

#### Participants

The present analyses are based on data obtained from 198 secondary mathematics teachers in Germany. Participants taught mathematics in 10th-grade classes sampled within the framework of a nationally representative student achievement study (cf. Kunter et al., 2007). Thus, our teacher sample can be considered fairly representative of 10th-grade mathematics teachers in Germany. Of the 198 teachers, 85 (55% male) taught at the academic-track GY, and 113 (43% male) at other secondary school types (NGY; e.g., Realschule, Sekundarschule). The average age of participating teachers was 47.2 years ( $SD = 8.4$ ); 46.4 years ( $SD = 9.1$ ; range 28–65) in the GY group and 47.8 years in the NGY group ( $SD = 7.7$ ; range 28–62). Teachers were paid 60 Euro (approximately US \$60 at the time of the survey) for their participation.

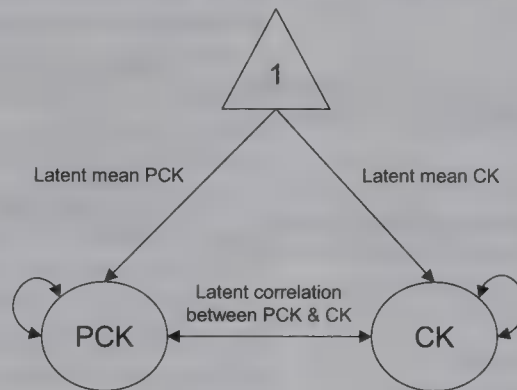

#### Assessment of PCK and CK

*PCK test.* In line with our theoretical framework, the PCK test contained three subscales: knowledge of mathematical tasks (Task), knowledge of student misconceptions and difficulties (Student), and knowledge of mathematics-specific instructional strategies (Instruction). Because the potential of tasks for students' learning can be exploited by considering various solution paths (e.g., Silver, Ghouseini, Gosen, Charalambous, & Strawhun, 2005), we assessed knowledge of tasks by testing teachers' awareness of multiple solution paths: four items required teachers to list as many different ways of solving the task as possible. Knowledge of student misconceptions and difficulties was assessed by presenting teachers with seven scenarios and asking them to detect, analyze (e.g., give cognitive reasons for a comprehension problem), or predict a typical student error or a particular comprehension difficulty. Knowledge of subject-specific instructional strategies was assessed by 10 items requiring teachers to explain mathematical situations (e.g., to provide useful representations, analogies, illustrations, or examples to make mathematical content accessible to students). Sample items for the three PCK subscales (Task, Student, Instruction) are displayed in Figure 2, along with sample responses scoring 1.

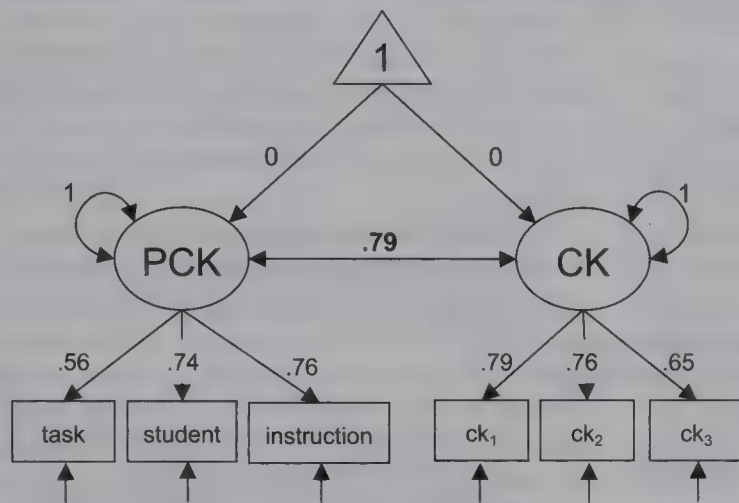

*CK test.* We conceptualized content knowledge as in-depth background knowledge on the contents of the secondary-level mathematics curriculum. Thirteen items were constructed to cover relevant content areas (e.g., arithmetic, algebra, and geometry) and to tap conceptual or procedural skills (Figure 2 presents a sample item).

*Scoring scheme.* All 34 items assessing PCK and CK were open ended. Items with no response or an incorrect response were scored 0; each correct answer was scored 1 (for items requiring several answers, e.g., the multiple solution tasks, the sum of the correct answers was calculated). Each test item was coded by two trained raters independently; in the event of rater disagreement, consensus was reached through discussion. The interrater reliability

Model fit indices and standardized model parameters are shown for (b) and (c). SRMR values below .08, RMSEA values below .05, and CFI values above .95 can be considered indicative of a good model fit. PCK = pedagogical content knowledge; CK = content knowledge; GY = Gymnasium; NGY = non-Gymnasium; SRMR = standardized root mean residual; RMSEA = root-mean-square error of approximation; CFI = comparative fit index.

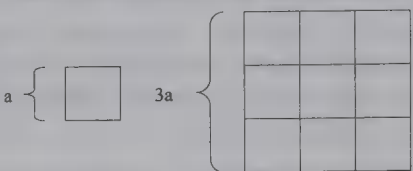

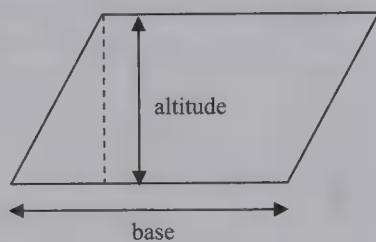

Knowledge Category (Subscale)	Sample Item	Sample response (scoring 1)
PCK Task	<p>How does the surface area of a square change when the side length is tripled? Show your reasoning.</p> <p>Please note down as many different ways of solving this problem (and different reasonings) as possible.</p>	<p><u>Algebraic response</u>            Area of original square: <math>a^2</math>            Area of new square is then <math>(3a)^2 = 9a^2</math>; i.e., 9 times the area of the original square.</p> <p><u>Geometric response</u>            Nine times the area of the original square</p> 
PCK Student	<p>The area of a parallelogram can be calculated by multiplying the length of its base by its altitude.</p>  <p>Please sketch an example of a parallelogram to which students might fail to apply this formula.</p>	 <p>Note: The crucial aspect to be covered in this teacher response is that students might run into problems if the foot of the altitude is outside a given parallelogram.</p>
PCK Instruction	<p>A student says: I don't understand why <math>(-1) \cdot (-1) = 1</math></p> <p>Please outline as many different ways as possible of explaining this mathematical fact to your student.</p>	<p>The "permanence principle," although it does not prove the statement, can be used to illustrate the logic behind the multiplication of two negative numbers and thus foster conceptual understanding:</p> $  \begin{array}{rcl}  3 \cdot (-1) & = & -3 \\  2 \cdot (-1) & = & -2 \\  1 \cdot (-1) & = & -1 \\  0 \cdot (-1) & = & 0 \\  (-1) \cdot (-1) & = & 1 \\  (-2) \cdot (-1) & = & 2  \end{array}  $ <p>Diagram showing a sequence of numbers from 3 down to -2, with arrows indicating the transition from positive to negative and back to positive, illustrating the permanence principle.</p>
CK	<p>Is it true that <math>0.999999... = 1</math> ?</p> <p>Please give detailed reasons for your answer.</p>	<p>Let <math>0.999... = a</math>            Then <math>10a = 9.99...</math>, hence,  <math>10a - a = 9.99... - 0.999...</math></p>  <p>Therefore <math>a = 1</math>; hence, the statement is true</p>

Figure 2. Sample items and corresponding sample responses (scoring 1) from the three subscales of the pedagogical content knowledge (PCK) test (Task, Student, Instruction) and from the content knowledge (CK) test.

ity  $\rho$  (Shavelson & Webb, 1991) was satisfactory (on average,  $\rho$  was .81 with  $SD = .17$ ).

**Procedure.** The assessment of PCK and CK was conducted individually in a separate room at the teacher's school on a workday afternoon. It was administered by a trained test administrator, as a power test with no time constraints. The average time required to complete the 34 items was about 2 hr (approx. 65 min

for the PCK instrument and 55 min for the CK instrument). The teachers were not allowed to use calculators.

#### Statistical Analysis of the PCK-CK Measurement Model

To investigate the structure of knowledge, we employed a confirmatory factor analysis in which the two knowledge catego-

ries were conceptualized as latent constructs based on manifest indicators. The sample size required for structural equation modeling in general and for confirmatory factor analysis in particular has been a matter of some debate. Some scholars recommend a sample size of at least  $N = 200$ ; others argue that no general recommendations can be made because sample size depends strongly on the properties of the model investigated and the data to be analyzed (cf. Jackson, 2003; Marsh, Hau, Balla, & Grayson, 1998). Another way of approaching the issue is to ensure a certain ratio of estimated parameters to participants. Some authors suggest a ratio of at least 1:5 (cf. Marsh et al., 1998). Given the 34 items in our tests (21 measuring PCK and 13 measuring CK), a PCK–CK (item factor) model in which each of the constructs is measured by the respective items would give a ratio of about 1:3, which is unacceptable.

To guarantee that the conclusions derived from our models are valid given our relatively small sample size of  $N = 198$  teachers, we therefore used subscale scores and parcel scores rather than items as manifest indicators (Little, Cunningham, Shahar, & Widaman, 2002), thus reducing the number of parameters to be estimated (e.g., instead of 34, there are just 6 factor loadings; see Figure 1b). This reduction in parameter numbers is particularly relevant for the second part of the analysis, in which the sample is divided into two groups. The latent knowledge construct PCK was measured by the three subscale scores, which were calculated by summing the corresponding item scores. The latent knowledge construct CK was measured by three parcel scores (Little et al., 2002). A preliminary exploratory factor analysis did not identify specific and interpretable subdimensions of CK, but showed that the CK items form one single factor. Therefore, four items with the same stem were assigned to one parcel ( $ck_3$ ) to account for potential task-specific variance that is represented in the corresponding residual term. The remaining nine (unidimensional) items were randomly divided into two further parcels ( $ck_1$  and  $ck_2$ ) following Little et al. (2002).

To tackle the question of empirical distinguishability, we first analyzed the PCK–CK model across all teachers (see Figure 1b), investigating the latent correlation between the two knowledge categories. We then specified a multigroup model (see Figure 1c) to address differences between the two groups of teachers. Although our sample size of  $N = 198$  teachers was sufficient to analyze the PCK–CK model across all teachers (yielding a ratio of about 1:10; see Figure 1b), the multigroup model (Figure 1c) requires closer inspection (here the ratio is about 1:6). Although a ratio of 1:6 seems reasonable, the sample size for the multigroup model is at the lower limit. We therefore investigated the power of the statistical analyses conducted. Table 1 lists the four null hypotheses,  $H_{01}$ – $H_{04}$ , that were central to our statistical analyses.  $H_{01}$  is the null hypothesis stating that PCK and CK do not constitute separable knowledge categories and are not distinguishable in the whole teacher sample.  $H_{02}$  and  $H_{03}$  are the null hypotheses corresponding to our research Hypothesis 1, and  $H_{04}$  is the null hypothesis corresponding to our research Hypothesis 2. Whereas  $H_{01}$  can be seen as a restriction on the model across all teachers (see Figure 1b),  $H_{02}$ – $H_{04}$  can be seen as particular restrictions on the multigroup model (see Figure 1c). Power can be defined as the probability to reject the null hypothesis when it is wrong. Taking this perspective, we followed the methodological recommendations of Satorra and Saris (1985) and calculated within the latent

Table 1  
Power Analysis ( $N = 198$ ;  $\alpha = .05$ )

Null hypotheses to reject	$\Delta\chi^2$	$\Delta df$	Power
$H_{01}$ latent correlation $r_{PCK, CK}$ is 1 in the total teacher sample	20.57	1	0.99
$H_{02}$ latent mean of PCK is identical in both groups of teachers	37.80	1	0.99
$H_{03}$ latent mean of CK is identical in both groups of teachers	106.28	1	1.00
$H_{04}$ latent correlation $r_{PCK, CK}$ is identical in both groups of teachers	6.91	1	0.75

Note. PCK = pedagogical content knowledge; CK = content knowledge.

variable framework the power to reject the null hypotheses  $H_{01}$ – $H_{04}$  given our sample size of  $N = 198$ . To this end, we specified “null models” for  $H_{01}$ – $H_{04}$  (e.g., for  $H_{01}$ , the latent correlation in Figure 1b, was set to 1). The chi-square difference test statistic that results from subtracting the chi-square test statistic of the original model (e.g., the latent correlation in Figure 1b is .79) from the chi-square test statistic of the corresponding “null model” represents the noncentrality parameter that is necessary to calculate statistical power from a noncentral chi-square distribution according to Satorra and Saris (1985). As shown in Table 1, the statistical power to test our hypotheses was acceptable with a sample size of  $N = 198$ .

Before comparing the latent means and correlations of two groups, we had to investigate whether the constructs measured have the same meaning in both groups. In the structural equation literature, it is standard procedure to run a series of invariance tests when doing multigroup comparisons to establish measurement equivalence by showing that (a) a model with factor loadings and intercepts of the manifest variables constrained to be equal across groups fits reasonably well (scalar invariance) and (b) the fit of the scalar invariant model is not much worse than that of a configural invariant or a metric invariant model that imposes fewer equality constraints across groups (Little, 1997; Vandenberg & Lance, 2000). In a configural invariant model, the factorial structure is assumed to be the same across groups; however, factor loadings and intercepts may differ. In the metric invariant model, the factorial structure and factor loadings are assumed to be identical across groups; however, the intercepts may vary. When local misfit is identified in one of these models, the corresponding equality constraint can be relaxed, and a partial invariant model may allow the same conclusions to be drawn as the full invariant model (Byrne, Shavelson, & Muthén, 1989). Our results (see Table 2) show that the fit of the metric invariant model was considerably worse than that of the configural invariant model. However, freeing the factor loading of  $ck_3$  in group GY led to a substantial improvement in model fit (partial metric invariance). The fit of the partial scalar invariant model (without equality constraint on the factor loading of  $ck_3$ ) was worse than that of the partial metric invariant model. The cause of the misfit was the invariance constraint on the intercept of  $ck_3$ . When this intercept was freely estimated in the GY group, the fit of the partial invariant model

Table 2  
*Series of Models Investigating Measurement Equivalence for the Multigroup Model*

Model	$\chi^2$	df	p	CFI	RMSEA	SRMR	$\Delta\chi^2$	$\Delta df$
M1. Configural invariance	15.79	16	.47	1.00	.00	.04

\*\*\*  $p < .001$ .

improved and became acceptable (see Table 2). According to Byrne et al. (1989), the partial scalar invariant model, which is presented in Figure 1c, guarantees measurement equivalence; the model can therefore be used to investigate our primary research questions. Furthermore, additional power analyses showed that our sample size yielded a statistical power of at least .99 to distinguish between the models reported in Table 2.

Analyses were run with the Mplus 4.2 software package (L. K. Muthén & Muthén, 1998–2006). Because prior analyses indicated that the distributions of five of the six sum scores (all but the subtest Instruction) deviated from normal distributions (skewness ranged from  $-.65$  to  $.82$ ; kurtosis ranged from  $-1.09$  to  $.07$ ), parameters were computed using the robust maximum likelihood estimator MLM, which is recommended for nonnormally distributed data (L. K. Muthén & Muthén, 1998–2006).

Results

Before we address our core hypotheses on the level and connectedness of PCK and CK in the two groups of teachers, we report the psychometric properties of our test scales and examine the general distinguishability of the two knowledge categories in the whole sample of teachers.

*Psychometric Properties of PCK and CK and Descriptive Information*

To give a first impression of measurement quality, we report the psychometric properties of the overall PCK (21 items) and CK (13 items) scales, which were analyzed by means of parameters derived from classical test theory. Both overall scale scores showed satisfactory reliability, with a Cronbach's alpha of  $\alpha = .77$  for the PCK scale and  $\alpha = .83$  for the CK scale. The items forming each scale discriminated adequately as evident from their (part-whole corrected) item-total correlations (PCK:  $M = .33$ , range:  $.17$  to  $.45$ ; CK:  $M = .48$ ; range:  $.30$  to  $.66$ ). The means and standard deviations for the subscale scores of PCK and the parcel scores of CK are given in Tables 3 and 4, along with the respective intercorrelations. Table 3 shows these descriptives for the whole teacher sample; Table 4, for the GY and NGY groups separately. In sum, these analyses indicate that the newly developed tests succeeded in

reliably assessing the knowledge categories PCK and CK in secondary mathematics teachers.

*Distinguishability of PCK and CK*

Figure 1b presents the results (parameter estimations and fit indices) for the PCK–CK model across all teachers. The fit of the model, as well as the valence and size of the factor loadings, indicates that the structure of teachers' professional knowledge is accurately captured by two latent constructs representing PCK and CK. The latent correlation between PCK and CK was rather high, at  $.79$ , indicating that teachers with higher CK also tend to have higher PCK. To test statistically whether CK and PCK are distinguishable constructs, we estimated a model in which the correlation between CK and PCK was constrained to 1. This led to a statistically significant decline in model fit, as shown by the chi-square difference test,  $\Delta\chi^2(1, N = 198) = 20.57, p < .001$ . Hence, from the perspective of inferential statistics, it can be concluded that, despite their rather high correlational interdependence, CK and PCK represent different constructs, at least when all teachers are considered together.

Table 3  
*Measures of Teachers' Professional Knowledge (Subscales and Parcels): Correlations and Descriptive Statistics for the Total Teacher Sample*

Correlations	Task	Student	Instruction	ck <sub>1</sub>	ck <sub>2</sub>	ck <sub>3</sub>
PCK

SD	2.16	1.98	3.34	1.32	1.27	1.50

Note. Task, Student, and Instruction are the subscales of pedagogical content knowledge (PCK); ck<sub>1</sub>, ck<sub>2</sub>, and ck<sub>3</sub> are the parcels of content knowledge (CK).

Table 4  
*Measures of Teachers' Professional Knowledge (Subscales and Parcels): Correlations and Descriptive Statistics by Teacher Group*

Correlations	Task	Student	Instruction	ck <sub>1</sub>	ck <sub>2</sub>	ck <sub>3</sub>
<b>PCK</b>						
Task		.28	.39	.34	.30	.11
Student	.48		.53	.44	.26	.11
Instruction	.40	.47		.46	.55	.24
<b>CK</b>						
ck <sub>1</sub>	.22	.23	.23		.43	.04
ck <sub>2</sub>	.18	.36	.30	.46		.21
ck <sub>3</sub>	.30	.29	.33	.44	.38	
<b>NGY</b>						
<i>M</i>	6.60	4.27	6.96	1.18	0.96	1.88
<i>SD</i>	2.02	1.85	3.16	0.97	1.02	1.50
<b>GY</b>						
<i>M</i>	7.45	5.81	9.08	2.84	2.16	3.51
<i>SD</i>	2.27	1.80	3.19	1.11	1.23	0.88
<b>Cohen's <i>d</i></b>						
(mean GY vs. NGY)	0.40	0.85	0.67	1.60	1.08	1.28

*Note.* The correlations for Gymnasium (GY) and non-Gymnasium (NGY) teachers are above and below the diagonal, respectively; Task, Student, and Instruction are the subscales of pedagogical content knowledge (PCK); ck<sub>1</sub>, ck<sub>2</sub>, and ck<sub>3</sub> are the parcels of content knowledge (CK); positive *d* values indicate that GY teachers outperformed NGY teachers. According to Cohen (1992), *d* = .3 represents a small effect, *d* = .5 represents a medium effect, and *d* = .8 represents a large effect. All mean differences are significant at *p* < .01.

### *Level of Knowledge and Cognitive Connectedness in the Two Groups of Teachers*

As expected, GY teachers and NGY teachers differed substantially in their mean levels of knowledge (Table 4 gives the means, standard deviations, and intercorrelations of the manifest measures for each teacher group separately). As indicated by Cohen's *d*, the group differences were particularly pronounced in the CK parcels, substantiating our assumption that GY teachers show much deeper mathematical understanding. This finding was further corroborated by the results of the multigroup model, in which PCK and CK were estimated as latent constructs in both groups simultaneously, thus eliminating measurement error (Figure 1c). The results show that GY teachers clearly have a more extensive knowledge base than NGY teachers in both knowledge categories. The latent means of the GY group (PCK: .99, CK: 2.01) were substantially higher than those of the NGY group (fixed to 0 for both constructs; cf. Little, 1997). The corresponding effect sizes were *d* = 1.00 for latent PCK and *d* = 2.15 for latent CK. These differences were statistically significant, as confirmed by two separate chi-square difference tests between the model depicted in Figure 1c and models in which the latent means of CK or PCK, respectively, were constrained to be the same (i.e., 0) across groups (CK:  $\Delta\chi^2[1, N = 198] = 106.28, p < .001$ ; PCK:  $\Delta\chi^2[1, N = 198] = 37.80, p < .001$ ), thus corroborating research Hypothesis 1.

Most important, the multigroup model showed that the two teacher groups differed not only in their knowledge level, but also in the structure of their knowledge base. As Figure 1c shows, the findings also supported research Hypothesis 2, that cognitive connectedness is dependent on the level of mathematical expertise: the latent correla-

tion between CK and PCK was .96 in the GY group and .61 in the NGY group. The statistical significance of the difference between these correlations was again confirmed in a chi-square difference test,  $\Delta\chi^2(1, N = 198) = 6.91, p < .05$ , thus showing a substantially higher degree of cognitive connectedness between the two knowledge categories for teachers in the GY group.

Given the extremely high correlation between PCK and CK in the group of GY teachers, the question arises of whether Shulman's (1986, 1987) two subject-specific knowledge categories are in fact empirically distinguishable in this group of highly knowledgeable teachers. To address this question, we compared the multigroup model (Figure 1c) with a model in which the correlation between the two constructs was fixed to 1 for the GY group. The chi-square difference test between the two nested models was not significant,  $\Delta\chi^2(1, N = 198) = 0.14, p = .72$ , indicating that the two knowledge categories form one body of connected knowledge and that PCK and CK are almost indistinguishable in the group of GY teachers. By contrast, when the correlation between the two constructs was fixed to 1 for the NGY group, the chi-square difference was significant,  $\Delta\chi^2(1, N = 198) = 20.38, p < .001$ , indicating that the two knowledge categories are separate in the group of NGY teachers.

The results thus demonstrate that the two groups of teachers, whose university education differed substantially, differ in both the level and structure of their knowledge. However, we cannot yet rule out the possibility that this finding is simply a manifestation of differences that existed between the groups prior to their teacher training. Although both teacher training tracks have the same formal requirements (Abitur qualification, no entrance exams), it is reasonable to assume that higher achieving students tend to opt to teach at Gymnasium. We investigated this possibility by looking at the teachers' own Abitur grade (which corresponds to the U.S. grade-point average), which was assessed in a biographical questionnaire (the Abitur grade was *z*-standardized for our analyses, with higher values indicating a better grade). The GY teachers indeed had substantially higher Abitur grades than the NGY teachers (NGY: *M* = -.22, *SD* = 1.03; GY: *M* = .26, *SD* = .92; *d* = .49, *p* < .001). To test whether this difference might explain the differences found between the two teacher groups to some degree (Figure 1c), we reran the analyses, with mean differences in the Abitur grade between the two groups of teachers being partialled out of the manifest indicators (subscale scores and parcel scores). The latent means and correlations obtained in the multigroup model were thus adjusted for the mean differences in the Abitur grade. The findings confirmed the pattern of results from our previous analyses: the mean differences found between the two teacher groups were of similar magnitude (standardized latent means of the GY teachers (PCK: .88, *d* = .88; CK: 1.79, *d* = 1.95), as were the latent correlations between PCK and CK (GY: *r* = .94, NGY: *r* = .60). Although the Abitur grade is just one indicator of prior differences, these analyses suggest that, even given the same levels of prior knowledge, it is only in GY teachers that pedagogical content knowledge and content knowledge fuse to form one inseparable category of knowledge.

### *Discussion*

In previous studies, most conclusions about the nature of teachers' knowledge have been drawn using indicators that are rather distal to the concept, such as university grades, number of subject matter courses taken at university (cf. Hill et al., 2005), or questionnaire data on beliefs or subjective theories (cf. Pajares, 1992). Consequently,

numerous calls have been made in the literature for more valid and reliable assessments of teacher knowledge (e.g., Lanahan et al., 2004). In the present study, we constructed and implemented tests to assess the pedagogical content knowledge and content knowledge of secondary mathematics teachers directly. We took a subject-specific approach, thus responding to repeated calls in the literature for general educational psychological theories to be specified for specific school subjects (e.g., Mayer, 2004b); here, for mathematics. Both knowledge categories were measured reliably, the fit for a corresponding structural model was satisfactory, and the mean differences between teachers with different educational backgrounds provided evidence for the empirical validity of the tests.

Our findings provide further evidence for the applicability of Shulman's (1986, 1987) taxonomy of teacher knowledge in empirical settings. More specifically, being informed by literature on expertise research, they offer a possible interpretation for previous inconclusive findings on the distinguishability of CK and PCK (Hill et al., 2004; Kahan et al., 2003; Phelps & Schilling, 2004). Our findings show that the degree of cognitive connectedness between PCK and CK in secondary mathematics teachers is a function of the degree of mathematical expertise. Capitalizing on the quasi-experimental situation of teacher training in Germany, which allowed us to identify teachers with different levels of mathematical expertise, we found that it was not possible to distinguish the two knowledge categories empirically in the high-expertise group of GY teachers, but that this distinction was clearly visible in the group of NGY teachers. Our findings are thus consistent with findings from other domains of expertise research showing that higher expertise often involves stronger integration of different knowledge categories, or "encapsulated knowledge" (Schmidt & Boshuizen, 1992). Consequently, subject-specific knowledge seems to form a common body of expertise in GY teachers, with high levels of CK and PCK alike. Given that GY teacher candidates receive additional in-depth mathematics training at university, but no additional training in teaching mathematics (relative to NGY teacher candidates), their substantially higher PCK scores are remarkable, and may—although very tentatively—be interpreted as a first indication that CK supports the development of PCK.

Practically, our results have at least two implications. First, our instrument might find more widespread application as a psychometric assessment tool that measures teachers' competence directly. In the light of recent developments in the area of teacher education, selection, and accountability—which have raised questions about the competences to be transmitted in teacher education, how schools or districts can evaluate the quality of their teachers, and how to provide teachers with feedback on their strengths and weaknesses—this aspect is of increasing importance. To date, most assessments of teacher quality rely on distal indicators such as university courses, degrees, or grades (Zumwalt & Craig, 2005). Our research identifies another way of gauging teacher qualifications in terms of the assets that seem most important for their primary task of teaching. Due to its pioneer character, our instrument is not yet suitable for use in high-stakes situations that require utmost reliability in identifying different levels of competence. We do not yet know enough about issues such as retest reliability or suitability for other samples, but addressing these questions is an important objective of our ongoing research agenda.

Second, our study provides some valuable insights into the "long arm" of university teacher training. Although our analyses suggest that the two teacher groups probably differed in certain background variables even prior to teacher training, they also

indicate that there must be something specific about either GY teacher training or professional development at GY schools—over and above the different starting levels—that facilitates more extensive knowledge development in this context. Moreover, because no positive correlation was found between years of teaching practice and the two knowledge categories (see Brunner et al., 2006), teacher training can be assumed to be at the core of the development of the two knowledge categories. Future research may be able to provide deeper insights into the acquisition of PCK and CK during teacher training. For instance, longitudinal implementation of our tests at several critical stages in teacher education might provide more accurate information on the timing (e.g., in which phase of teacher education are PCK and CK acquired?) and mechanisms (e.g., which is needed to acquire the other?) of professional expertise development. Such studies may help to create instructional programs (at university and in the classroom) to foster the CK and PCK of student teachers, and to monitor their learning progress with respect to these knowledge categories.

The limitations of our study raise further interesting research questions. First, our study can only provide limited insights into the external validity of our measures. The finding that the teachers with more in-depth training in mathematics scored significantly higher in the content knowledge test may be seen as a first indication of the measure's external validity, but other approaches to the validity issue are also required. For instance, the convergent and discriminant validity of our measures should be investigated by employing our instrument in combination with other direct measures of mathematics teachers' professional knowledge (e.g., the newly developed standardized PRAXIS series; Educational Testing Service, 2006). Even more important, because our knowledge measures were assessed in a standardized testing situation, their implications for authentic learning situations remain to be investigated. Additional research is needed to examine precisely how PCK and CK regulate teaching behavior, and crucially their impact on student learning. Drawing on previous studies (e.g., Fennema & Franke, 1992; Ma, 1999), teachers with higher PCK might be expected to display a broader repertoire of instructional strategies and to be more likely to create cognitively stimulating learning situations. Indeed, first empirical findings indicate that teachers with higher PCK scores on our test tend to set tasks with higher potential for cognitive activation but do not seem to differ from their peers in terms of classroom management (Kunter et al., 2007). These findings provide first evidence for the discriminant validity of our instrument (for the approach of investigating the construct validity of PCK and CK by examining other populations, e.g., subject-matter experts or biology and chemistry teachers, with the tests, see Krauss, Baumert, & Blum, in press). Finally, strictly speaking, the generalizability of our results is limited to secondary mathematics teachers in Germany. Before final conclusions can be drawn about the dimensionality of teacher knowledge, our results need to be replicated in other samples; for instance, with teachers from countries with different educational systems. Last but not least, it is our hope that the present article might not only activate discussion on the professional knowledge of mathematics teachers, but also initiate similar endeavors for other school subjects.

# Instructions to Authors

## Journal of Educational Psychology

www.apa.org/journals/edu

The main purpose of the *Journal of Educational Psychology* is to publish original, primary psychological research pertaining to education across all ages and educational levels. A secondary purpose of the *Journal* is the occasional publication of exceptionally important theoretical and review articles that are pertinent to educational psychology.

**Manuscript preparation.** Authors should prepare manuscripts according to the *Publication Manual of the American Psychological Association* (5th ed.). Manuscripts may be copyedited for bias-free language (see chap. 2 of the *Publication Manual*). Formatting instructions (all copy must be double-spaced) and instructions on the preparation of tables, figures, references, metrics, and abstracts appear in the *Manual*. For APA's Checklist for Manuscript Submission, see [www.apa.org/journals](http://www.apa.org/journals). **Abstract and keywords.** All manuscripts must include an abstract containing a maximum of 180 words typed on a separate page. After the abstract, please supply up to five keywords or brief phrases. **References.** References should be listed in alphabetical order. Each listed reference should be cited in text, and each text citation should be listed in the References. Basic formats are as follows:

Haag, L., & Stern, E. (2003). In search of the benefits of learning Latin. *Journal of Educational Psychology*, 95, 174–178.

Bollen, K. A. (1989). *Structural equations with latent variables*. New York: Wiley.

Johnson, D. W., & Johnson, R. T. (1990). Cooperative learning and achievement. In S. Sharon (Ed.), *Cooperative learning: Theory and research* (pp. 173–202). New York: Praeger.

Adequate description of participants is critical to the science and practice of educational psychology; this allows readers to assess the results, determine generalizability of findings, and make comparisons in replications, extensions, literature reviews, or secondary data analyses. Authors should see guidelines for sample–subject description in the *Manual*. Appropriate indexes of effect size or strength of relationship should be incorporated in the results section of the manuscript (see pp. 5, 25–26 of the *Manual*). Information that allows the reader to assess not only the significance but also the magnitude of the observed effects or relationships clarifies the importance of the findings. **Figures.** Graphics files are welcome if supplied as Tiff, EPS, or PowerPoint. High-quality printouts or glossies are needed for *all* figures. The minimum line weight for line art is 0.5 point for optimal printing. When possible, please place symbol legends below the figure image instead of to the side. Original color figures can be printed in color at the editor's and publisher's discretion provided the author agrees to pay \$255 for one figure, \$425 for two figures, \$575 for three figures, \$675 for four figures, and \$55 for each additional figure.

**Publication policies.** APA policy prohibits an author from submitting the same manuscript for concurrent consideration by two or more publications. APA policy regarding posting articles on the Internet may be found at [www.apa.org/journals](http://www.apa.org/journals). In addition, it is a violation of APA Ethical Principles to publish "as original data, data that have been previously published" (Standard 8.13). As this is a primary journal that publishes original material only, APA policy prohibits publication of any manuscript or data that have already been published in whole or substantial part elsewhere. Authors have an obligation to consult journal editors concerning prior publication of any data on which their article depends. In addition, APA Ethical Principles specify that "after research results are published, psychologists do not withhold the data on which their conclusions are based from other competent professionals who seek to verify the substantive claims through reanalysis and who intend to use

such data only for that purpose, provided that the confidentiality of the participants can be protected and unless legal rights concerning proprietary data preclude their release" (Standard 8.14). Authors must have available their data throughout the editorial review process and for at least 5 years after the date of publication.

**Masked review policy.** The *Journal* has a masked review policy, which means that the identities of both authors and reviewers are masked. Every effort should be made by the authors to see that the manuscript itself contains no clues to their identities. Authors should never use first person (*I, my, we, our*) when referring to a study conducted by the author(s) or when doing so reveals the authors' identities, e.g., "in our previous work, Johnson et al., 1998 reported that . . ." Instead, references to the authors' work should be in third person, e.g., "Johnson et al. (1998) reported that . . ." The authors' institutional affiliations should also be masked in the manuscript. Authors submitting manuscripts are required to include in the cover letter the title of the manuscript along with all authors' names and institutional affiliations. However, the first page of the manuscript should omit the authors' names and affiliations, but should include the title of the manuscript and the date it is submitted. Responsibility for masking the manuscript rests with the authors; manuscripts will be returned to the author if not appropriately masked. If the manuscript is accepted, authors will be asked to make changes in wording so that the paper is no longer masked. Authors are required to state in writing that they have complied with APA ethical standards in the treatment of their sample, or to describe the details of treatment. A copy of the APA Ethical Principles may be obtained at [www.apa.org/ethics/](http://www.apa.org/ethics/) or by writing the APA Ethics Office, 750 First Street, NE, Washington, DC 20002-4242. APA requires authors to reveal any possible conflict of interest in the conduct and reporting of research (e.g., financial interests in a test procedure, funding by pharmaceutical companies for drug research). Authors of accepted manuscripts will be required to transfer copyright to APA.

**Permissions.** Authors of accepted papers are required to obtain and provide to the editor on final acceptance all necessary permissions to reproduce in print and electronic form any copyrighted work, including, for example, test materials or portions thereof and photographs of people.

**Supplemental materials.** APA can now place supplementary materials online, which will be available via the published article in the PsycARTICLES database. To submit such materials, please see [www.apa.org/journals/authors/suppmaterial.html](http://www.apa.org/journals/authors/suppmaterial.html) for details. Authors of accepted papers will be asked to work with the editor and production staff to provide supplementary materials as appropriate.

**Submission.** Authors should submit their manuscripts electronically via the Manuscript Submission Portal at [www.apa.org/journals/edu](http://www.apa.org/journals/edu) (follow the link "Submit Manuscripts Electronically"). A checklist for manuscript submission, including guidelines for preparing the electronic file, can be found at [www.apa.org/journals/](http://www.apa.org/journals/). Correspondence regarding manuscripts should be sent to the Editor, Art Graessen, University of Memphis, Journal of Educational Psychology, 202 Psychology Building, Memphis, TN 38152-3230. In addition to addresses and phone numbers, authors should supply e-mail addresses, as most communications will be by e-mail. Fax numbers, if available, should also be provided for potential use by the editorial office and later by the production office. Authors should keep a copy of the manuscript to guard against loss. E-mail correspondence may be addressed to [jedgar@memphis.edu](mailto:jedgar@memphis.edu).

**Preparing files for production.** If your manuscript is accepted for publication, please follow the guidelines for file formats and naming provided at [www.apa.org/journals/authors/preparing\\_efiles.html](http://www.apa.org/journals/authors/preparing_efiles.html). If your manuscript was mask reviewed, please ensure that the final version for production includes a byline and full author note for typesetting.

# WORKING WITH PARENTS OF NONCOMPLIANT CHILDREN

## A GUIDE TO EVIDENCE-BASED PARENT TRAINING FOR PRACTITIONERS AND STUDENTS

**Mark D. Shriver and Keith D. Allen**

**T**his book presents an in-depth look at evidence-based programs for training parents of children with behavior problems. Authors Mark D. Shriver and Keith D. Allen review the empirical support for four major programs, as well as some more popular programs that lack strong empirical support. Throughout this review they teach readers how to identify the best research in parent training, how to prepare for parent training sessions, and finally show how to translate this research into everyday practice.

Parents usually are the most influential people in a child's life. So when child problems like noncompliance, hyperactivity, sleep problems, feeding problems, toileting problems, academic problems, and adolescent-parent conflict arise it is important for parents to take on the primary role in their resolution. This book explains *what* parents are taught when collaborating with a psychologist or counselor and *how* they are taught effectively. Practitioners, whether they are experienced, new to parent training, or students of the field, will find this book to be a valuable resource for taking interventions developed under tightly controlled research conditions and adapting them to the conditions of day-to-day practice, where resources are more limited and presenting problems are often more complex. 2008. 280 pages. Hardcover.

**Series: Applying Psychology to the Schools (Division 16)**

**CONTENTS:** Preface ■ Introduction ■ **Part I: Searching for the Best Available Evidence** ■ Chapter 1. Parenting and Parent Training ■ Chapter 2. Empirically Supported Parent Training Programs ■ Chapter 3. Evaluating the Scientific Merit of Parent Training Alternatives ■ **Part II: Developing Clinical Expertise** ■ Chapter 4. Conceptual Foundations of the Empirically Supported Parent Training Programs ■ Chapter 5. How to Teach Parents ■ Chapter 6. Cultural Issues in Parent Training ■ **Part III: Integrating and Translating Research Into Everyday Practice** ■ Chapter 7. Beyond Noncompliance: Developing Evidence-Based Parent Training Interventions ■ Chapter 8. Delivering Evidence-Based Parent Training: From Research to Practice ■ Chapter 9. Parent Training: Prevention and Future Research ■ References

### APA Dictionary of Psychology

With over 25,000 terms and definitions, the *Dictionary* encompasses all areas of research and application, and includes coverage of concepts, processes, and therapies across all the major subdisciplines of psychology. Ten years in the making and edited by a distinguished editorial board of nearly 100 psychological scholars, researchers and practitioners, the *APA Dictionary of Psychology* is destined to become the **most authoritative** reference of its kind.

*"This is an excellent reference work that should be ordered by every institutional library and every psychology department to make it accessible to students, faculty, researchers, and practitioners in all social science and health-related arenas."*

— **PsycCRITIQUES**

*"For the world's largest and most well known association of psychologists to produce a dictionary gives the work an 'out of the box' authority and prestige that few works share... Summing up: Essential."* — **Choice**

*"Ten years in the making, the American Psychological Association's (APA) new dictionary was well worth the wait."* — **Library Journal**, starred review

The main purpose of the *Journal of Educational Psychology* is to publish original, primary psychological research pertaining to education across all ages and educational levels. A secondary purpose of the *Journal* is the occasional publication of exceptionally important theoretical and review articles that are pertinent to educational psychology.

**Change of Address:** Send change of address notice and a recent mailing label to the attention of Subscriptions Department, APA, 30 days prior to the actual change of address. APA will not replace undelivered copies resulting from address changes; journals will be forwarded only if subscribers notify the local post office in writing that they will guarantee periodicals forwarding postage.

**Single Issues, Back Issues, and Back Volumes:** For information regarding single issues, back issues, or back volumes, write to Order Department, American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242.

**Microform Editions:** For information regarding microform editions, write to University Microfilms, Ann Arbor, MI 48106.

**Manuscripts:** Effective in January 2008, the Incoming Editor is receiving all new submissions to the journal. Submissions that are accepted will be published beginning in the 2009 volume. Submit manuscripts electronically via the Manuscript Submission Portal at <http://www.apa.org/journals/edu/submission.html> according to the Instructions to Authors (see the table of contents). The opinions and statements published are the responsibility of the authors, and such opinions and statements do not necessarily represent the policies of APA or the views of the Editor.

**Copyright and Permission:** Those who wish to reuse APA-copyrighted material in a non-APA publication must secure from APA and the author of the material written permission to reproduce a journal article in full or journal text of more than 800 cumulative words or more than 3 tables or figures. APA normally grants permission contingent on permission of the author, inclusion of the APA copyright notice on the first page of reproduced material, and payment of a fee of \$25 per page. Permission from APA and fees are waived for those who wish to reproduce a single table or figure from a journal for use in a print product, provided the author's permission is obtained and full credit is given to APA as copyright holder and to the author through a complete citation. (Requesters requiring written permission for commercial use of a single table or figure will be assessed a \$25 service fee.) Permission and fees are waived for authors who wish to reproduce their own material for personal use; fees only are waived for authors who wish to use more than a single table or figure of their own material commercially (but for use in edited books, fees are waived for the author only if serving as the book editor). Permission and fees are waived for the photocopying of isolated journal articles for nonprofit classroom or library reserve use by instructors and educational institutions. A permission fee may be charged to the requester if students are charged for the material, multiple articles are copied, or large-scale copying is involved (e.g., for course packs). Access services may use unedited abstracts without the permission of APA or the author. Libraries are permitted to photocopy beyond the limits of the U.S. copyright law: (1) post-1977 articles, provided the per-copy fee in the code for this journal (0022-0663/08/\$12.00) is paid through the Copyright Clearance Center, 222 Rosewood Drive, Danvers, MA 01923; (2) pre-1978 articles, provided that the per-copy fee stated in the Publishers' Fee List is paid through the Copyright Clearance Center. Address requests for reprint permission to Permissions Office, American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242.

**Electronic Access:** APA members who subscribe to this journal have automatic access to all issues of the journal in the PsycARTICLES® full-text database. See <http://my.apa.org/access.html>.

**Reprints:** Authors may order reprints of their articles from the printer when they receive proofs.

**APA Journal Staff:** Susan J. A. Harris, *Senior Director, Journals Program*; Skip Maier, *Director, Journal Services*; Paige W. Jackson, *Director, Editorial Services*; Clark Munsell, *Account Manager*; Jodi Ashcraft, *Director, Advertising Sales and Exhibits*.

The **Journal of Educational Psychology** (ISSN 0022-0663) is published quarterly (February, May, August, November) in one volume per year by the American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242. Subscriptions are available on a calendar year basis only (January through December). The 2009 rates follow: *Nonmember Individual*: \$159 Domestic, \$184 Foreign, \$194 Air Mail. *Institutional*: \$490 Domestic, \$532 Foreign, \$545 Air Mail. *APA Member*: \$76. Write to Subscriptions Department, American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242. Printed in the U.S.A. Periodicals postage paid at Washington, DC, and at additional mailing offices. POSTMASTER: Send address changes to the *Journal of Educational Psychology*, American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242.

# Effect of Retention in First Grade on Children's Achievement Trajectories Over 4 Years: A Piecewise Growth Analysis Using Propensity Score Matching

Wei Wu and Stephen G. West  
Arizona State University

Jan N. Hughes  
Texas A&M University

The authors investigated the relatively short-term and longer term effects of grade retention in 1st grade on the growth of mathematics and reading achievement over 4 years. The authors initially identified a large multiethnic sample ( $n = 784$ ) of children who were below the median in literacy at school entrance. From this sample, the authors closely matched 1 retained with 1 promoted child ( $n = 97$  pairs) on the basis of propensity scores constructed from 72 background variables and compared growth of retained and promoted children using Rasch-modeled W scores and grade standard scores, which facilitate age-based and grade-based comparisons, respectively. When using W scores, retained children experienced a slower increase in both mathematics and reading achievement in the short term but a faster increase in reading achievement in the longer term than did the promoted children. When using grade standard scores, retained children experienced a faster increase in the short term but a faster decrease in the longer term in both mathematics and reading achievement than did promoted children. Some of the retention effects were moderated by limited English language proficiency, home-school relationship, and children's externalizing problems.

**Keywords:** grade retention, growth curve model, propensity score, optimal matching, achievement

Since the mid-1990s, “ending social promotion” has become a central component of the standards-based reform movement that emphasizes setting content-based standards for students and holding both schools and students accountable for meeting them. In his 1998 and 1999 State of the Union addresses, President Clinton urged an end to social promotion and stated that scores on standardized tests should be the basis for promotion. The No Child Left Behind federal legislation passed in 2001, championed by President George W. Bush, requires that assessments aligned with state standards be used to measure the achievement of all children at each grade level. States increasingly use performance on these tests to evaluate schools and to reach decisions about promotion of children to the next grade.

Texas, the location of the present study, has been a leader in the standards-based reform movement. In 1990, the Texas legislature enacted a policy requiring all schools to test students in Grades 3 and higher with a test aligned with statewide curricular standards. Schools are evaluated on the basis of performance on this test, currently the Texas Assessment of Knowledge and Skills; test results are widely publicized; and rewards and sanctions are allo-

cated to schools on the basis of performance standards. In 1999, Texas enacted legislation that took effect in the 2002–2003 school year that requires students in Grades 3, 5, and 8 to pass the Texas Assessment of Knowledge and Skills in specified content areas to be promoted to the next grade, unless certain exceptional circumstances apply (e.g., documented learning disability). These policies were initiated by then-Governor George W. Bush and served as the model for the No Child Left Behind federal legislation.

Although the effectiveness of these educational accountability policies is hotly disputed (Evans, Baugh, & Sheffer, 2005; Hong & Raudenbush, 2005; Sipple, Killeen, & Monk, 2004; Warren & Edwards, 2005), there is little doubt that one consequence of the use of high-stakes testing is a decrease in the frequency of social promotion (defined as promoting to the next grade children who have not mastered curriculum content at their current grade) and an increase in grade retention (Gootman, 2005; Roderick, Bryk, Jacob, Easton, & Allensworth, 1999; Roderick & Nagaoka, 2005). In Texas, retention rates in Grades K–5 increased from 1994–1995 to 2003–2004, with the retention rate for Grade 3, the first promotional gate grade, up 100% over this time period (Texas Education Agency, 2005). The accountability movement likely affects retention policies even when performance on the curriculum-aligned test is not the sole or primary criterion for grade retention decisions. In Texas in 2003–2004, retention in first grade, the focal grade in this study, was 6.4%, compared with 5.8% in 1994–1995 (Texas Education Agency, 2005).

## Previous Research on Retention Effects

When a student has failed to demonstrate grade-level competencies, one option is to retain the student in hopes that another

year of maturity and exposure to the curriculum of the repeated grade will prepare the child to meet the academic and social demands of the next grade, thereby increasing the probability of academic and social success in future grades. Despite the intuitive appeal of the argument for grade retention as an intervention for poor achievement, the weight of available empirical evidence of varying methodological quality collected over 50 years suggests that grade retention either bestows no benefits on the retained student or has a negative impact on achievement and on social and emotional adjustment, self-confidence, and attachment to school (Dennebaum & Kulberg, 1994; Hong & Raudenbush, 2005; McCoy & Reynolds, 1999; Miesels & Liaw, 1993; Pagani, Tremblay, Vitaro, Boulerice, & McDuff, 2001; Reynolds & Bezruczko, 1993). Meta-analytic investigations of the published literature report overall negative effects of grade retention (Holmes, 1989; Holmes & Matthews, 1984; Jimerson, 2001). Grade retention has also been associated with a substantial increase in school withdrawal before high school completion (Jimerson, 1999; Roderick, 1994), even when retained students' academic performance is similar to that of comparably low-achieving promoted peers (Alexander, Entwisle, & Dauber, 2003).

Because children are not randomly assigned to the retention intervention, some critics (e.g., Hong & Raudenbush, 2005; Reynolds, 1992) have argued that many of the available studies that compare the postretention performance of retained children with that of nonselected promoted children tell us little about the impact of grade retention. Since the 1980s, the majority of studies on the effect of grade retention have compared the performance of retained students with that of low-achieving promoted peers. These studies have used two types of comparisons: (a) same-grade comparisons and (b) same-age comparisons. Same-grade comparisons evaluate retained and promoted students when they are in the same school grade. Thus, the performance of retained children is compared with promoted students who are, on average, a year younger. Alternatively, a proxy for this direct same-grade comparison can be used in which retained and promoted students are compared with extensive norms based on children in the same school grade. In contrast, same-age comparisons compare retained and nonretained children directly on measures of performance. Thus, the performance of retained children is compared with that of promoted students who are the same age but who will be one grade ahead of the target children. Both types of comparisons are informative, but they clearly answer different questions.

Results of these studies have been mixed, with some studies finding positive effects for achievement (Alexander, Entwisle, & Dauber, 1994; Mantzicopoulos & Morrison, 1992) and others reporting no effects or negative effects (Miesels & Liaw, 1993; Pianta, Tietbohl, & Bennett, 1997; Reynolds, 1992). When positive effects are reported, they are typically short-term effects that diminish within 2 or more years after the repeat year (Pierson & Connell, 1992). Studies using same-age comparisons compare the outcomes of retained children with those of children deemed at risk for promotion who were, nevertheless, promoted to the next grade. Results of these studies are more consistent in documenting negative effects of grade retention (Dennebaum & Kulberg, 1994; Hong & Raudenbush, 2005; Jimerson, 1999).

Despite the large number of published studies investigating the effects of grade retention, methodological limitations of these studies provide a weak basis for reaching conclusions about the

impact of grade retention. The basic problem is the challenge of making causal inferences in the absence of a randomized experimental design (West & Thoenmes, 2008). It is neither feasible nor ethically appropriate to randomly assign students to the "treatments" of retention and promotion. A large number of variables at the child, family, school, and district level are associated with the treatment selection (i.e., retention versus promotion) and with the measured outcomes (Reynolds, 1992; Willson & Hughes, 2006). Because of this potential selection bias, a finding that retained children experience more negative outcomes at some future point in their academic careers, compared with all promoted children, may often tell us little about the effect of retention on these outcomes. Whereas some researchers have made no attempt to control for preretention differences, in recent years researchers have attempted to deal with this confounder in one or both of two ways.

In the first approach, researchers compare the performance of retained students with that of a comparison group of students who were deemed as being at risk for being retained but who were promoted. The typical approach is to select students in the same grade as the retained students who scored below a specific score (e.g., below the 25th or 50th percentile) on a measure of achievement or cognitive ability during that year, but who were promoted to the next grade the subsequent year. Some studies using this approach document equivalent performance for retained and promoted students on preretention measures. Unfortunately, there is no guarantee with this approach that the promoted and retained groups are fully equivalent on the measured variable. In addition, potential differences between promoted and retained children on other important variables known to be related to school performance (e.g., child hyperactivity, parental education level, and peer acceptance) may exist. These sources of nonequivalence from selection bias confound the interpretation of the effects of retention on outcomes (Reichardt, 2006).

In the second approach, statistical adjustments are made for a limited number of preretention variables, using analysis of covariance or, equivalently, multiple regression (Cohen, Cohen, West, & Aiken, 2003; Huitema, 1980). These statistical adjustment procedures make three key assumptions. First, the limited number of covariates that can be included in the model adequately capture the important preexisting differences between the retained and promoted groups. Second, the relationship (typically linear) between each covariate and the outcome is correctly specified. Third, the regression lines for the retained and nonretained groups are parallel. Researchers have rarely reported checking these critical assumptions, nor have they used alternative procedures that relax one or more of them (see, e.g., Little, Hyonggin, Johanns, & Giordani, 2000). In addition, when groups are disparate at pretest, the application of statistical adjustment procedures often assumes that the effect of the treatment (retention) can be extrapolated beyond the region in which the baseline data for the two groups actually overlap, often a very risky procedure (Shadish, Cook, & Campbell, 2002; Shadish, Luellen, & Clark, 2006).

During the past 2 decades, a new method of equating groups, propensity score analysis (McCaffrey, Ridgeway, & Morral, 2004; Rosenbaum, 2002; Rosenbaum & Rubin, 1983; Shadish et al., 2006; West & Thoenmes, 2008), has been extensively developed in statistics. Propensity score analysis offers important benefits over previous equating approaches, and it has begun to be used in

applied research on important social issues in which randomization is not possible. In this approach, participants are measured on a wide variety of baseline measures believed on the basis of prior substantive theory and research to be related to treatment selection, the outcome variable, or ideally both. To the extent that researchers have identified the important variables related to both treatment selection and outcome, it is possible to remove baseline differences between treatment groups and achieve unbiased estimates of treatment effects. A statistical model is used to estimate a single propensity score for each participant, the predicted probability that the participant will be in the treatment (retention) condition. Typically, logistic regression using all measured baseline variables as predictors is used for this step, although other, more complicated statistical models are occasionally needed.<sup>1</sup> The propensity score is then used to equate the treatment and control groups using matching, blocking (creating strata), or analysis of covariance. Both statistical theory (Rosenbaum, 2002; Rosenbaum & Rubin, 1983) and empirical research (Shadish & Clark, 2006) have shown that the use of propensity scores substantially reduces or eliminates selection bias when properly used. Careful use of propensity scores achieves approximate balance on the baseline levels of each of a comprehensive set of measured variables. Hong and Raudenbush (2005) recently introduced propensity score methods as a device to equate retained and promoted children in studies of grade retention.

### Study Purpose

The purpose of the current study was to combine three methods that help maximize the internal validity of nonrandomized studies to examine the effect of retention in first grade on children's growth in reading and math over a 4-year period, beginning with the child's 1st year in first grade. First, before any of the children were retained, we selected and comprehensively assessed a sample of children at risk for retention on the basis of their scores below the 50th percentile on school district tests of reading. Second, we used propensity score matching, which corrects for selection bias, using an extensive, carefully chosen set of variables measured at baseline. Third, we used growth curve modeling that permits estimation of each child's trajectory of growth in mathematics and reading achievement. With four waves of data, we can examine the effects of retention on both short-term and longer term growth in math and reading achievement. Specifically, we used piecewise linear trajectory models (Singer & Willett, 2003) to investigate both immediate and longer term effects. We expected the slope for retention effects in the interval from Year 1 through Year 2 would differ from that in the interval from Year 2 through Year 4 for the retained children. Otherwise stated, we could compare the differences in the growth of the retained and promoted children in the short term, when retained children are repeating the first-grade curriculum, and in subsequent years, when retained and promoted children are exposed to novel curriculum at new grade levels.

We analyzed achievement results using both grade-level standard scores and W scores (a Rasch-type measure of ability) from the Woodcock-Johnson III (WJ-III), a well-researched, nationally standardized measure of reading and math achievement. Grade-level standard scores compare students with grade-level norms based on the student's current grade. W scores are a measure of actual growth in math and reading ability; comparisons between

retained and promoted children using W scores are comparable to age norms, in that retained children's rate of growth in the underlying, latent construct of math or reading is directly compared with that of promoted children for the same time interval. We expected that results would differ on the basis of whether grade standard scores or W scores were analyzed. Specifically, using grade standard scores, we expected retention would favor retained children during the short term but that the benefit would begin to dissipate when retained students were promoted to the second grade. Using W scores, we expected retention to favor promoted children in the short term, when promoted students are exposed to a new curriculum. We also hypothesized that the slopes representing the longer term growth for retained and promoted students would either be comparable (parallel) after the repeat year or, if the promise of retention were fulfilled, higher for retained students because of their stronger foundation in the content covered in the repeat grade.

Finally, we investigated whether several factors at various levels of analysis (i.e., child, family, and classroom) moderate the effects of grade retention. Consistent with developmental systems theory (Lerner, 1989), we expected that the impact of retention on a child's achievement trajectory would differ on the basis of the interplay of the retention "treatment" and factors at multiple levels of analysis, including factors within and outside the child (Cicchetti & Posner, 2005; Sameroff, 1975, 1989). Previous investigations of moderator variables have been restricted to distal demographic variables such as gender, race, or family socioeconomic status, with inconsistent findings (Pagani et al., 2001; Reynolds, 1992). We investigated more proximal child and classroom variables that were expected to moderate the effects of retention. Specifically, we examined children's behavioral regulation, as indexed by teacher, peer, and parent ratings of externalizing behaviors, child personality resilience, and teacher-student and home-school relationship quality. We expected that the relative benefit of promotion versus retention on children's achievement trajectories would be stronger for children with better behavioral regulation, greater personality resilience (agreeable, conscientious, and persistent), and more supportive teacher-student and home-school relationships. We reasoned that such child assets would enable children who are promoted, relative to their propensity-matched retained children, to successfully meet the greater maturity and academic demands of higher grades. We also tested age as a moderator because parents and educators are more likely to retain younger children for age, relative to similar low-achieving students (Mantzicopoulos, 2003; Reynolds, 1992; Willson & Hughes, 2006). Thus, it is important to evaluate the wisdom of using age as a selection factor for the retention treatment.

This study extends a previous study (Wu, West, & Hughes, 2008) with this sample. Because only three waves, or years, of data were available in the Wu et al. (2008) study, short-term and longer term change could not be investigated. That study found negative effects for retention on math W scores but no effects for reading W scores. Finally, the short-term beneficial effects of promotion were

<sup>1</sup> Logistic regression is the most commonly used method of estimating propensity scores, although other approaches such as regression tree methods can also be used (see McCaffrey et al., 2004, and West & Thommes, 2008, for a discussion of the major estimation methods).

stronger for children with good behavioral regulation and for children who were not classified as Limited English Proficient.

The current study analyzes both grade standard scores and W scores, whereas the previous study analyzed only W scores. The analysis of both W scores and grade standard scores permits us to answer two different questions. Specifically, because W scores are an interval-level measure of reading and math skills, their use permits a determination of the effect of grade retention on children's growth in achievement. Because grade standard scores compare a student's performance to grade-level norms for the same grade as that in which the student is enrolled, it permits a determination of the effect of grade retention on children's performance relative to the student's current grade placement. Both comparisons have merit (Alexander et al., 2003). By modeling both short-term and longer term effects and by analyzing both children's performance relative to grademates and children's actual growth in reading and math, we are able to render a more comprehensive picture of the impact of grade retention than has been possible in previous studies. Research by Miles and Stipek (2006) and Skinner, Zimmer-Gemback, and Connell (1998) has suggested that children's relative (rank order) level of achievement becomes relatively stable after Grade 3. Although their research did not investigate children's achievement trajectories, which is the focus of the present study, it does suggest that understanding the impact of early grade retention may potentially be important in the understanding of children's long-term achievement outcomes.

## Method

### Participants

Participants were drawn from a larger sample of children participating in a longitudinal study examining the impact of grade retention on academic achievement. Participants were recruited from three school districts in Texas (one urban and two small cities) across two sequential cohorts in first grade during the fall of 2001 and 2002. Children were eligible to participate in the longitudinal study if they scored below the median score on a state-approved district-administered measure of literacy, spoke either English or Spanish, were not receiving special education services, and had not previously been retained in first grade. School records identified 1,374 children as eligible to participate. Because teachers distributed consent forms to parents via children's weekly folders, the exact number of parents who received the consent forms cannot be determined. Incentives in the form of small gifts to children and the opportunity to win a larger prize in a random drawing were instrumental in obtaining 1,200 returned consent forms, of which 784 parents (65%) provided consent and 416 declined.

Analyses of a broad array of archival variables including performance on the district-administered test of literacy (standardized within district because of differences in the test used), age, gender, ethnicity, eligibility for free or reduced-price lunch, bilingual class placement, cohort, and school context variables (i.e., percentage ethnic or racial minority and percentage economically disadvantaged) did not indicate any differences between children with and without consent. The resulting sample of 784 participants (52.6% male) closely resembles the population from which they were drawn on demographic and literacy variables relevant to students'

educational performance. The ethnic composition of the achieved sample ( $N = 784$ ) was 37% Hispanic (39% of whom were Spanish language dominant), 34% White Caucasian, 23% African American, and 6% other; 62% of the children qualified for free or reduced-price lunch. The mean full scale IQ based on the Universal Nonverbal Intelligence Test (Bracken & McCallum, 1998) for the sample was 92.91 ( $SD = 18.01$ ), and the mean reading achievement score was 96.40 ( $SD = 14.28$ ).

Participants for the growth curve analyses were those 196 children (58% male) who were successfully matched with respect to their propensity to be retained in first grade (see description of propensity-matching procedures below) and who had achievement test scores for at least one of the four assessment periods. The racial and ethnic composition of the sample was 33% Caucasian, 33% Hispanic, 31% African American, and 3% other. At entrance to first grade, children's mean age was 6.46 ( $SD = 0.33$ ) years. Of the 196 matched cases (98 pairs), the proportions of children who completed the WJ-III were 96%, 85%, 86%, and 85%, respectively, at each of the four measurement waves.

### Design Overview

Demographic information including child age, gender, race or ethnicity, eligibility for free or reduced-price lunch, and status as Limited English Proficient were obtained from school district records. Teacher, parent, and peer data were collected in the spring of Year 1, when all participants were in first grade. Teachers and parents received \$25.00 for completing and returning the questionnaires. Peers' perceptions of the level of externalizing behaviors were obtained via individual interviews conducted between February and May of Year 1. Beginning in Year 1, annual measures of math and reading achievement were individually administered at school for 4 years, with the constraint that at least 8 months separated each annual assessment.

### Measures

A complete list of the 72 baseline variables collected at measurement Wave 1 used in calculation of propensity scores is available from Jan N. Hughes. The baseline variables included demographic measures, cognitive and behavioral performance, social and emotional functioning, and classroom and school variables. The 72 variables were intended to be as comprehensive as possible, including variables that have been shown in prior research to be related to early retention versus promotion, early academic achievement, or ideally both. The measures of academic achievement served as the primary outcome measures for this study. Selected baseline measures were used to explore potential moderator variables that might affect the rate of growth of children in response to retention versus promotion. These measures and the achievement measures are described below.

**Academic achievement.** The WJ-III Tests of Achievement (Woodcock, McGrew, & Mather, 2001) are individually administered measures of academic achievement for individuals ages 2 to adulthood. We used the WJ-III Broad Reading (Letter-Word Identification, Reading Fluency, and Passage Comprehension subtests) and Broad Math (Calculations, Math Fluency, and Math Calculation Skills subtests) W scores and grade standard scores. The Reading and Math W scores are based on the Rasch measurement

model, which ensures interval-level measurement of change on a single dimension.<sup>2</sup> Grade standard scores compare children's performance to grade-level national norms and only approximate an equal-interval measurement scale. Extensive research has documented the reliability and construct validity of the WJ-III and its predecessors (Woodcock & Johnson, 1989; Woodcock et al., 2001).

The Bateria Woodcock-Muñoz: Pruebas de Aprovechamiento—Revisada (Bateria-R; Woodcock & Muñoz-Sandoval, 1996) is the comparable Spanish version of the Woodcock-Johnson Tests of Achievement—Revised (WJ-R; Woodcock & Johnson, 1989), the precursor to the WJ-III. If children or their parents spoke any Spanish, children were administered the Woodcock-Muñoz Language Test (Woodcock & Muñoz-Sandoval, 1993) to determine the child's language proficiency in English and Spanish. The test of achievement (WJ-III or the Bateria-R) was chosen to match the language in which the child had greater proficiency. The Woodcock Compuscore (Woodcock & Muñoz-Sandoval, 2001) program yields W scores for the Bateria-R that are comparable to W scores on the WJ-R. In the following, scores are referred to as WJ scores (W or grade standard scores), irrespective of which test the child took.

*Teacher and parent report of conduct problems and hyperactivity.* Teachers and parents completed the Strengths and Difficulties Questionnaire (Goodman, 1997), a brief (25-item) screening measure for psychopathology. Each item is rated on a scale ranging from 0 to 2 (i.e., *not true*, *somewhat true*, and *certainly true*). The Strengths and Difficulties Questionnaire yields five scales consisting of 5 items each. The Conduct Problems and the Hyperactivity scales assess externalizing behaviors. For our sample, coefficient alpha for Conduct Problems was .84 for teachers and .71 for parents. For Hyperactivity, coefficient alpha was .89 for teachers and .81 for parents. In a sample of children participating in this longitudinal study, teacher reports of Conduct Problems and of Hyperactivity were moderately to strongly correlated with both parent report (.47 and .30, for conduct problems and hyperactivity, respectively) and peer reports (.50 and .46, for conduct problems and hyperactivity, respectively; Hill & Hughes, 2007). Exploratory and confirmatory factor analyses support the construct validity of the teacher and parent versions of the Strengths and Difficulties Questionnaire (Dickey & Blumberg, 2004; Goodman, 2001; Hill & Hughes, 2007).

*Peer nomination of externalizing problems.* Peers' perceptions of classmates' hyperactivity and aggression were obtained following procedures widely recommended in the peer assessment literature (Cillessen & Bukowski, 2000). Scores of similar constructs obtained from similar peer nomination procedures have demonstrated good reliability and validity (Realmuto, August, Sieler, & Pessoa-Brandao, 1997). In individual interviews, children were presented a roster with the names of all classmates. The interviewer read each of the classmates' names and asked the child whether he or she knew each child. Then the interviewer asked the child to nominate as few or as many classmates as he or she wished who fit each descriptor. Of interest to this study are the aggression item ("Some kids start fights, say mean things, or hit others") and the hyperactivity item ("Some kids do strange things and make a lot of noise. They bother people who are trying to work"). Each class member received an aggression and hyperactivity score based on the number of nominations that child received. Socio-

metric scores were standardized within classrooms. Because the two scores were highly correlated ( $r = .74$ ), we computed a composite peer-rated externalizing score as the mean standardized score on the aggression and hyperactivity items. Written parent consent was obtained for each child who participated in the sociometric interview. However, all children in a classroom were eligible to be rated or nominated. Terry (1999) reported that reliable and valid sociometric data can be collected using the unlimited nomination approach when as few as 40% of children in a classroom participate. We followed Terry's guideline, computing sociometric scores only for those 602 (77%) children located in classrooms in which more than 40% of classmates participated in the sociometric assessment. The mean rate of classmate participation in the sociometric administrations was .65 (range = .40 to .95). Elementary school children's peer nomination scores derived from procedures similar to those used in this study have been found to be stable over periods from 6 weeks to 4 years and to be associated with concurrent and future behavior and adjustment (for review, see Hughes, 1990).

*Resilient personality.* A confirmatory factor analysis (Kwok, Hughes, & Luo, 2007) on a sample of 445 first-grade children participating in the current longitudinal study supported a second-order measurement model of resilient personality defined by three first-order factors: Agreeableness (nine items), Conscientiousness (eight items), and Ego Resiliency (seven items). Agreeableness and Conscientiousness items were taken from the scales of the same name of the Big Five Inventory (John & Srivastava, 1999). Sample Agreeableness items include "is helpful and unselfish with others," "likes to cooperate with others," and "is sometimes rude to others" (reverse scored). Sample Conscientiousness items include "does a thorough job," "is a reliable worker," and "tends to be disorganized" (reverse scored). Coefficient alpha for each scale was .94. Ego Resiliency items were derived from items on the California Child Q-Sort (Caspi, Block, Block, & Klopp, 1992). Sample items include "resourceful in initiating necessary activities" and "falls to pieces under stress" (reverse scored). Teachers responded to each of the items using a 5-point scale. Coefficient alpha for our sample was .85. We computed a score for resilient personality as the mean of the standardized score for each scale.

*Teacher-student relationship quality.* The 22-item Teacher Student Relationship Inventory (Hughes, Cavell, & Willson, 2001) is based on the Network of Relationships Inventory (Buhrmester & Furman, 1987). Teachers indicated on a 5-point Likert-type scale their level of support (16 items, coefficient  $\alpha = .94$ ) or conflict (6 items, coefficient  $\alpha = .92$ ) in their relationships with individual students. Because the Support and Conflict scales were negatively correlated ( $-.57$ ), we recoded the Conflict items in the opposite direction. The coefficient alpha of the 22 items after recoding the Conflict items was .95. A total relationship quality score was computed as the mean of the 22 item scores. In a longitudinal study of behaviorally at-risk elementary school students, the Teacher Student Relationship Inventory Support score predicted changes in behavioral adjustment and peer relationships (Meehan, Hughes, & Cavell, 2003). In the larger sample, the Teacher Student Relationship Inventory

<sup>2</sup> In contrast, measures of reliability within classical test theory do not ensure that a single dimension has been measured or that interval-level measurement has been achieved.

predicted cross-year changes in children's achievement (Hughes & Kwok, 2006).

*Home-school relationship.* The Teacher Report of Parent Involvement Scale (Wong & Hughes, 2006) consists of 20 items assessing teachers' perceptions of the parent-teacher alliance (e.g., "I respect this parent" and "Communication between us is difficult"; reverse scored) and of the frequency of parents' engagement of various involvement activities (e.g., volunteering at school and calling the teacher). Coefficient alpha for the current sample was .87.

### Propensity Score Estimation

Propensity scores, the predicted probability of being retained in first grade, were estimated for the 768 children for whom retention information was available, using 72 background variables collected at the initial testing, including child demographic variables and child, peer, teacher, and parent data covering the areas of academic aptitude (e.g., the Universal Nonverbal Intelligence Test), academic achievement (WJ-III or the Spanish-language Batería-R broad math and reading), personality (e.g., agreeableness and effortful control), behavioral and social adjustment, peer relations, and family adversity. Methods based on logistic regression (Rosenbaum, 2002; Rosenbaum & Rubin, 1983) were used to estimate propensity scores. The larger the propensity score, the larger the predicted probability that the child would be retained in the first grade. For the 768 cases, the propensity score ranged from .0003 to .989 with a mean of .215 ( $SD = .215$ ). The children who were subsequently promoted had substantially lower propensity scores ( $n = 603$ ,  $M = .114$ ,  $SD = .166$ ) than those who were subsequently retained ( $n = 165$ ,  $M = .583$ ,  $SD = .309$ ),  $t(190.6) = -18.769$ , Cohen's  $d = -1.890$ . Although not the primary criterion in evaluating the success of the propensity model (see Rosenbaum 2002; Shadish et al., 2006), the logistic regression equation led to relatively good prediction of the decision to retain or promote each child with a Nagelkerke pseudo- $R^2$  index of .552 (see Cohen et al., 2003, p. 503).

Despite identifying an at-risk sample of children who were below the median on literacy at entrance to first grade, substantial differences existed between the retained and the promoted groups. These results indicated that an adjustment procedure would be needed to equate the retained and the promoted groups. Following the recommendations of West and Thoenes (2008; see also Rosenbaum, 2002), we chose a procedure that produces optimal matches on propensity scores.

### Matching Procedure

We matched 1 retained child with 1 promoted child on the basis of their propensity scores using SAS 8.0 PROC ASSIGN (Ming & Rosenbaum, 2001). PROC ASSIGN matches retained children with promoted children so that the sum of distance between the propensity scores within each of the matched pairs was minimized for the whole sample. To avoid matching two children with propensity scores far away from each other, we imposed a caliper distance of .025, the maximum distance in propensity scores allowed for a match to take place. That is, any pair of retained and promoted children who differed in their propensity scores by more than .025 could not be matched with each other. We chose a very small caliper distance to obtain high-quality matching. Using this method, a total of 98 pairs (196 children) were successfully

matched. For the 98 matched pairs, the propensity score ranged from .003 to .918 ( $M = .367$ ,  $SD = .225$ ). The mean within-pair distance in propensity score was .007 ( $SD = .008$ ). Following the optimal matching process, the two groups were closely equated on their propensity scores: For the promoted group,  $N = 98$  ( $M = .366$ ,  $SD = .225$ ), and for the retained group,  $N = 98$  ( $M = .367$ ,  $SD = .226$ ),  $t(194) = -0.044$ , *ns*, Cohen's  $d = -0.006$ . This outcome contrasts sharply with the substantial mean differences in the propensity scores between the promoted and retained groups in the full sample ( $N_{\text{promoted}} = 603$ ;  $N_{\text{retained}} = 165$ ). Table 1 reports descriptive information for the 98 pairs.

### Data Analysis

To investigate the relatively short-term and longer term effects of retention on the growth rate of WJ scores, we split the time span into two pieces at the point at which the measurement wave was 2 (the 2nd year of the study). The first piece included the measurements on Waves 1 and 2, which covers the change in WJ scores from roughly 0.5 year before retention to 0.5 year after retention. The second piece included the measurements on Waves 2, 3 and 4, which covers the change in WJ scores from roughly 0.5 year after retention to 2.5 years after retention. Then we fit a linear growth curve on each piece for the four WJ scores separately using SAS 8.0 PROC Mixed. Such growth curve models are called two-piece linear growth curve models (Singer & Willett, 2003). Given the existence of missing data, we used full information maximum likelihood estimation to estimate the growth curve models. Full information maximum likelihood estimation uses all of the observations available for each case to compute the likelihood function (Enders & Bandalos, 2001). It provides unbiased estimates with minimal standard errors when data are missing at random (Schafer & Graham, 2002). Otherwise stated, full information maximum likelihood estimation provides estimates that are appropriately corrected for all measured variables included in the analysis.

The specification of the two-piece linear growth curve model for any one of the WJ scores is shown in Equations 1 to 3, which includes three levels. Level 1 (within individual, Equation 1) captures the two-piece linear growth trajectory for each individual over the 4 years of the study. At Level 1, two time variables ( $T1_{\text{rip}}$  and  $T2_{\text{rip}}$ ), corresponding to the two pieces, were created to predict the WJ scores. To simplify the presentation, two coding schemes were adopted to create  $T1_{\text{rip}}$  and  $T2_{\text{rip}}$  as follows.

Coding Scheme 1:

	Wave 1	Wave 2	Wave 3	Wave 4
T1	0	1	1	1
T2	0	0	1	2

Coding Scheme 2:

	Wave 1	Wave 2	Wave 3	Wave 4
T1	0	1	2	3
T2	0	0	1	2

Following guidelines in Cohen et al. (2003, chap. 8), we used two coding schemes in the study even though their results are algebraically related and produce identical results for overall model fit and predicted values at each measurement wave. The use of the two schemes permitted us to conduct a significance test of

Table 1  
Descriptive Statistics of Selected Time 1 Measures

Note. *d* is reported as a measure of the standardized effect size for the difference between two means and *h* is reported as the standardized effect size for the difference between two proportions (Cohen, 1977). For both measures, Cohen suggested 0.2, 0.5, and 0.8 represented small, medium, and large effects, respectively. WJ-III = Woodcock-Johnson III.

each of the parameters of interest and to present the simplest possible interpretation of the results. Coding Scheme 1 allowed us to test the slope separately for each piece and furthermore to test whether the slopes in each piece differ between retained and promoted groups. However, Coding Scheme 1 does not permit us to test the significance of the difference in the change in slope between the short and longer term. That is one reason why we used Coding Scheme 2, which provides both this significance test and a test of whether the pattern of change in slope differs between the retained and the promoted groups. We centered time at Wave 1 (the point at which both  $T1_{tip}$  and  $T2_{tip}$  were coded 0); thus, the intercept represents the student's predicted level of WJ scores on the first wave of measurement (initial status in first grade before retention or promotion).

Level 2 (between individual, Equation 2) captures the variation in individual intercepts and slopes across individuals. At Level 2, we used grade retention status after first grade (coded 1 = retained, 0 = promoted) to predict the individual intercepts, individual slopes for the short term (Slope 1), and individual slopes for the longer term (Slope 2). Because matching produces dependency in the data, Level 3 (between pairs, Equation 3) was added to take into account the within-pair correlation for individual intercepts (clustering). This procedure adjusts for biased estimates of the standard errors caused by the dependency, thus leading to more accurate significance tests for the parameter estimates. The effects of retention on Slope 1 (short-term effect,  $\lambda_{110}$ ) and Slope 2 (longer term effect,  $\lambda_{210}$ ) are our primary interest. The equations for the three-level model are presented below.

$$\text{Level 1: } Y_{tip} = \pi_{0ip} + \pi_{1ip}T1_{tip} + \pi_{2ip}T2_{tip} + e_{tip};$$

$$e_{tip} \sim N(0, \sigma^2). \quad (1)$$

$$\text{Level 2: } \pi_{0ip} = \beta_{00p} + \beta_{01p}RETENTION_{ip} + r_{0ip};$$

$$\pi_{1ip} = \beta_{10p} + \beta_{11p}RETENTION_{ip}; \text{ and}$$

$$\pi_{2ip} = \beta_{20p} + \beta_{21p}RETENTION_{ip}; r_{0ip} \sim N(0, \tau_{\pi 00}). \quad (2)$$

$$\text{Level 3: } \beta_{00p} = \gamma_{000} + u_{00p}; \beta_{10p} = \gamma_{100}; \beta_{20p} = \gamma_{200};$$

$$\beta_{01p} = \gamma_{010}; \beta_{11p} = \gamma_{110}; \beta_{21p} = \gamma_{210}; u_{00p} \sim N(0, \tau_{\beta 00}). \quad (3)$$

Here the subscript *t* indicates time point (Wave 1, 2, 3, or 4), *i* indicates individual, and *p* indicates pair.  $\gamma_{000}$  and  $\gamma_{100}$  represent, respectively, the grand mean of the intercept and Slope 1 for the promoted group. Under Coding Scheme 1,  $\gamma_{200}$  represents the grand mean of Slope 2 for the promoted group. Under Coding Scheme 2,  $\gamma_{200}$  represents the average slope difference between the two pieces (Slope 2 – Slope 1) for the promoted group.  $\gamma_{010}$  and  $\gamma_{110}$  represent the estimated effects of grade retention in first grade on the intercept and Slope 1, respectively. Under Coding Scheme 1,  $\gamma_{210}$  represents the effect of grade retention on Slope 2, whereas under Coding Scheme 2,  $\gamma_{210}$  represents the effect of retention on the slope difference between the two pieces.  $e_{tip}$  represents the Level 1 residual for the *i*th individual within the *p*th pair at Wave *t*, which was assumed to follow a normal distribution with mean ( $\mu$ ) = 0 and homogeneous variance ( $\sigma^2$ ) across 4 years.  $\sigma^2$  is the within-individual variance in WJ scores that cannot be accounted for by time.  $r_{0ip}$  represents Level 2 residual in intercept for the *i*th individual within the *p*th pair, which was assumed to follow a normal distribution with  $\mu = 0$  and variance =  $\tau_{\pi 00}$ .  $\tau_{\pi 00}$  is the between-individual variance in intercept that cannot be accounted for by grade retention.  $u_{00p}$  represents the deviation of the mean intercept of the *p*th pair from the grand mean

intercept for promoted children, which was also assumed to follow a normal distribution with  $\mu = 0$  and variance =  $\tau_{\beta 00}$ .  $\tau_{\beta 00}$  is the between-pair variance in intercepts. Given that only four measurement waves were available to estimate a complex model, we assumed that there is neither between-individual residual variance nor between-pair variance in Slope 1 and Slope 2.

Next, the potential moderator variables were added into Level 2 of the growth model one at a time as shown in Equation 4. The moderating effects of these variables were captured by the coefficients associated with their interaction with grade retention ( $\gamma_{130}$  for Slope 1 and  $\gamma_{230}$  for Slope 2 with Coding Scheme 1). The moderating effects are assumed to be constant across matched groups (see Equation 5). We only used Coding Scheme 1 in the moderator analyses for ease of presentation because we could interpret the moderating effects on Slope 1 and Slope 2 separately.

Level 2:  $\pi_{0ip} = \beta_{00p} + \beta_{01p}RETENTION_{ip}$   
 $+ \beta_{02p}MODERATOR_{ip}$   
 $+ \beta_{03p}MODERATOR_{ip} \times RETENTION_{ip}$   
 $+ r_{0ip};$   
 $\pi_{1ip} = \beta_{10p} + \beta_{11p}RETENTION_{ip} + \beta_{12p}MODERATOR_{ip}$   
 $+ \beta_{13p}MODERATOR_{ip} \times RETENTION_{ip};$  and  
 $\pi_{2ip} = \beta_{20p} + \beta_{21p}RETENTION_{ip} + \beta_{22p}MODERATOR_{ip}$   
 $+ \beta_{23p}MODERATOR_{ip} \times RETENTION_{ip}.$  (4)

Level 3:  $\beta_{00p} = \gamma_{000} + u_{00p}; \beta_{10p} = \gamma_{100}; \beta_{20p} = \gamma_{200};$   
 $\beta_{01p} = \gamma_{010}; \beta_{02p} = \gamma_{020}; \beta_{03p} = \gamma_{030};$   
 $\beta_{11p} = \gamma_{110}; \beta_{12p} = \gamma_{120}; \beta_{13p} = \gamma_{130};$   
 $\beta_{21p} = \gamma_{210}; \beta_{22p} = \gamma_{220}; \beta_{23p} = \gamma_{230}.$  (5)

Here  $\gamma_{000}$ ,  $\gamma_{100}$ , and  $\gamma_{200}$  represent the estimated mean intercept, Slope 1, and Slope 2 for the promoted group with 0 value on moderator, respectively;  $\gamma_{010}$ ,  $\gamma_{110}$ , and  $\gamma_{210}$  represent the main effects of grade retention on the intercept and slope, respectively;  $\gamma_{020}$ ,  $\gamma_{120}$ , and  $\gamma_{220}$  represent the main effects of moderator on the intercept, Slope 1, and Slope 2, respectively; and  $\gamma_{030}$ ,  $\gamma_{130}$ , and  $\gamma_{230}$  represent the interaction effects of moderator and retention on the intercept, Slope 1, and Slope 2, respectively. The interpreta-

tions of Level 1 and Level 2 residuals are similar with the model without moderator included.  $u_{00p}$  represents Level 3 deviations of pair mean intercepts from the grand mean intercept for promoted children with a value of 0 on the moderator.

Results

Table 2 presents the estimates for parameters of theoretical interest obtained from the two-piece linear growth models (see Equations 1 to 3). The first two sets of results examine the effects of retention using WJ W scores for math and reading, which implicitly compare the children’s performance to that of age-mates. The second two sets of results examine the WJ grade standard scores for math and reading, which compare the children’s performance to that of grade-mates. For ease of presentation, in the following we use  $s1_P$  and  $s2_P$  to represent Slope 1 (short term) and Slope 2 (longer term) for promoted children and  $s1_R$  and  $s2_R$  to represent Slope 1 and Slope 2 for retained children.

WJ W Scores

*WJ math W score.* As shown in Table 2, both Slope 1 and Slope 2 were positive for promoted children ( $s1_P = 16.09$ , Wald  $z = 16.67$ ,  $p < .001$ ;  $s2_P = 9.28$ , Wald  $z = 18.20$ ,  $p < .001$ ), indicating that there was an increase on WJ math W score in both pieces for promoted children, but that the increase for promoted children in the longer term was slower than the increase in the short term. Subsequent grade retention was not associated with the initial status in first grade (Wald  $z = 0.18$ , *ns*), indicating that matching on propensity scores achieved initial equivalence of the promoted and retained groups on WJ math W score. Grade retention had a negative effect on Slope 1 ( $s1_R - s1_P = -6.20$ , Wald  $z = -4.83$ ,  $p < .001$ ), indicating that in the short term, the retained children had a lower annual rate of gain of 6.20 points on the WJ math W score than did the promoted children. To put this gain in context, the normative annual gain on the WJ math W score is 9.17 for children ages 8–9. In contrast, grade retention had no significant effect on Slope 2 (Wald  $z = 1.04$ , *ns*), indicating that the annual rate of gain on the WJ math W score in the longer term did not differ significantly between the retained and promoted groups.

Coding Scheme 2 focuses on slope differences between the two pieces. Grade retention had a positive effect on the slope difference between the two pieces ( $[s2_R - s1_R] - [s2_P - s1_P] = 6.97$ , Wald  $z = 3.67$ ,  $p < .001$ ). Slope 1 and Slope 2 differed by  $-6.81$  for promoted

Table 2  
Selected Parameter Estimates for the Two-Piece Linear Growth Curve Model Without Moderators

Parameter	WJ-III math W score	WJ-III reading W score	WJ-III math grade score	WJ-III reading grade score
Intercept for promoted	459.37* (1.24)	424.70* (2.17)	98.53* (1.40)	92.33* (1.56)
Slope 1 for promoted	16.09* (0.97)	35.75* (1.66)	1.65 (1.12)	4.06* (1.21)
Slope 2 for promoted	9.28* (0.51)	12.64* (0.87)	0.01 (0.59)	-1.61* (0.64)
(Slope 2 – Slope 1) for promoted	-6.81* (1.31)	-23.11* (2.25)	-1.64 (1.52)	-5.67* (1.64)
Effect of retention on intercept	0.31 (1.73)	-1.18 (2.94)	-1.68 (1.97)	-4.01 (2.13)
Effect of retention on Slope 1	-6.20* (1.41)	-10.16* (2.40)	12.23* (1.63)	15.54* (1.75)
Effect of retention on Slope 2	0.77 (0.74)	4.77* (1.26)	-3.04* (0.86)	-2.47* (0.93)
Effect of retention on (Slope 2 – Slope 1)	6.97* (1.90)	14.93* (3.25)	-15.27* (2.20)	-18.02* (2.37)

Note. Standard errors are in parentheses. WJ-III = Woodcock-Johnson III.  
\*  $p < .05$ .

children ( $s2_P - s1_P = -6.81$ , Wald  $z = -5.20$ ,  $p < .001$ ), whereas the rate of growth did not change across the short and longer term for retained children ( $s2_R - s1_R = 0.16$ , *ns*). These results are illustrated in Figure 1A, which portrays the estimated two-piece linear growth lines for the overall retained and promoted groups.

**WJ reading W score.** Similar to the WJ math W score, there was an increase on WJ reading W score in both the short and the longer term for promoted children ( $s1_P = 35.75$ , Wald  $z = 21.54$ ,  $p < .001$ ;  $s2_P = 12.64$ , Wald  $z = 14.53$ ,  $p < .001$ ). Subsequent grade retention was not associated with initial status in first grade (Wald  $z = -0.69$ , *ns*) of the WJ reading W score. This provides further evidence of the success of the propensity score-matching procedure. Grade retention had a negative effect on Slope 1 ( $s1_R - s1_P = -10.16$ , Wald  $z = 4.23$ ,  $p < .001$ ), whereas it had a positive effect on Slope 2 ( $s2_R - s2_P = 4.77$ , Wald  $z = 3.79$ ,  $p < .001$ ), indicating that in the short term, the average annual rate gain on WJ reading W score for retained children was 10.16 points lower than that for promoted children, whereas in the longer term, retained children had an annual rate gain of 4.77 points higher on WJ reading W score than did promoted children (see Figure 1B). To put this gain in context, the normative annual gain on the WJ reading W score is 14.32 for children ages 8–9. Combining the two results using Coding Scheme 2, grade retention was found to have a positive effect on the slope difference between the two pieces ( $[s2_R - s1_R] - [s2_P - s1_P] = 14.93$ , Wald  $z = 4.59$ ,  $p < .001$ ). Slope 1 and Slope 2 differ by  $-23.11$  ( $s2_P - s1_P = -23.11$ , Wald  $z = -10.27$ ,  $p < .001$ ) for promoted children, whereas they only differed by  $-8.18$  ( $s2_R - s1_R = -8.18$ ) for retained

children. These results indicate that compared with promoted children, retained children showed a smaller reduction in slope from the short term to the longer term for WJ reading W score.

### WJ Grade Standard Scores

**WJ math grade score.** For promoted children, neither Slope 1 nor Slope 2 was significantly different from 0 ( $s1_P = 1.65$ , Wald  $z = 1.47$ , *ns*;  $s2_P = 0.01$ , Wald  $z = .02$ , *ns*). Promoted children showed nearly no change in WJ math grade standard score across 4 years. Once again, subsequent grade retention was not associated with initial status of WJ math grade score (Wald  $z = 0.85$ , *ns*). Grade retention showed a positive effect on Slope 1 ( $s1_R - s1_P = 12.23$ , Wald  $z = 7.50$ ,  $p < .001$ ), but a negative effect on Slope 2 ( $s2_R - s2_P = -3.04$ , Wald  $z = -3.53$ ,  $p < .001$ ). This finding indicates that rather than keeping a constant rate of growth relative to grademates on WJ math, as did promoted children, retained children showed a dramatic increase in the short term (the repeat year) and decreased markedly on WJ math relative to their grademates in the longer term as they encountered new material (see Figure 1C). Combining these results using Coding Scheme 2, grade retention had a negative effect on the slope difference between two pieces ( $[s2_R - s1_R] - [s2_P - s1_P] = -15.27$ , Wald  $z = -6.94$ ,  $p < .001$ ). Slope 1 and Slope 2 did not differ for promoted children ( $s2_P - s1_P = -1.64$ , Wald  $z = -1.08$ , *ns*). However, Slope 2 was significantly lower than Slope 1 for retained children ( $s2_R - s1_R = -16.91$ ).

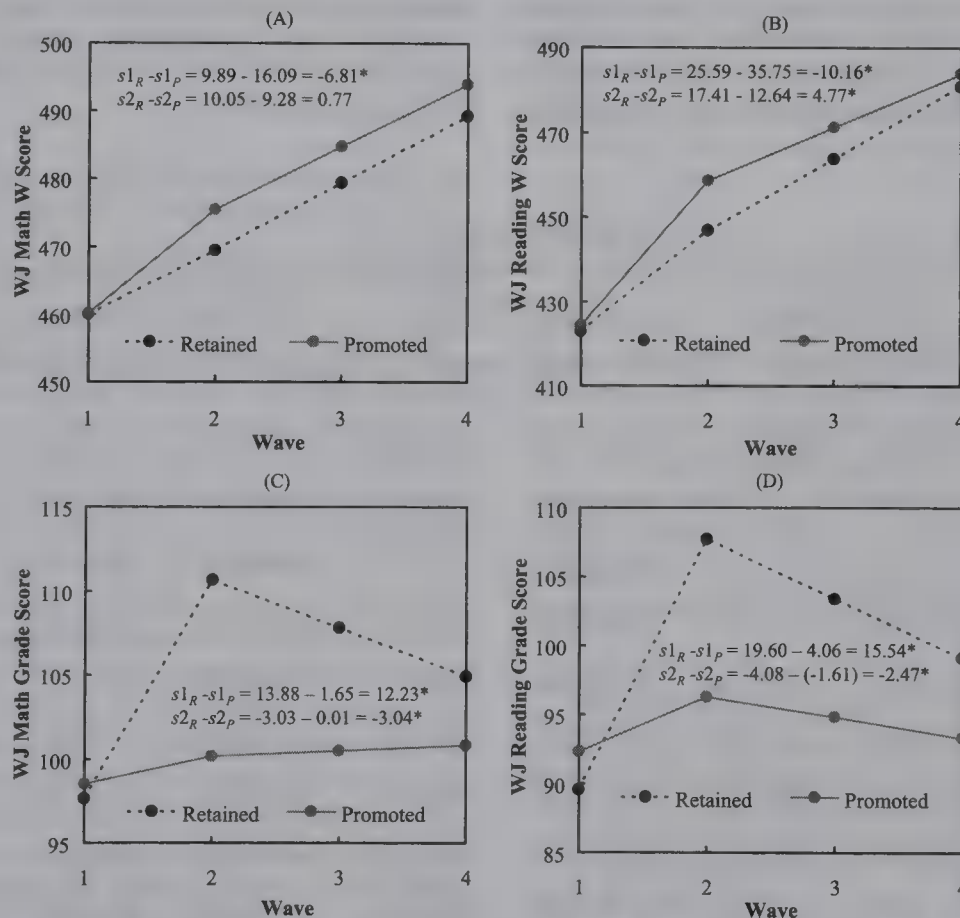

Figure 1. Estimated two-piece linear growth curves of the four WJ scores.  $s1_P$  and  $s2_P$  represent the slopes in the short and longer terms for promoted children, and  $s1_R$  and  $s2_R$  represent the slopes in the short and longer terms for retained children. WJ = Woodcock-Johnson III. \*  $p < .05$ .

*WJ reading grade score.* For promoted children, Slope 1 was positive ( $s1_P = 4.06$ , Wald  $z = 3.36$ ,  $p < .001$ ), whereas Slope 2 was negative ( $s2_P = -1.61$ , Wald  $z = -2.52$ ,  $p = .01$ ). This result indicates that for promoted children, there was an increase on WJ reading grade score in the short term followed by a slight yearly decrease on WJ reading grade score in the longer term. Again, subsequent grade retention was not associated with a significant effect on the initial status for WJ reading grade score in first grade (Wald  $z = 1.88$ , *ns*). Grade retention showed similar effects on Slope 1 and Slope 2 for WJ reading grade score as for the WJ math grade score. The effect of grade retention on Slope 1 was positive ( $s1_R - s1_P = 15.54$ , Wald  $z = 8.88$ ,  $p < .001$ ), which indicates that retained children showed an average higher annual rate gain of 15.54 points on WJ reading grade score in the short term (see Figure 1D). In contrast, the effect of grade retention on Slope 2 was negative ( $s2_R - s2_P = -2.47$ , Wald  $z = -2.66$ ,  $p = .01$ ).

Focusing now on slope differences between the two pieces using Coding Scheme 2, we found that grade retention had a negative effect on the slope difference between the two pieces ( $[s2_R - s1_R] - [s2_P - s1_P] = -18.02$ , Wald  $z = -7.60$ ,  $p < .001$ ). For promoted children, Slope 2 was 5.67 points smaller than Slope 1 ( $s2_P - s1_P = -5.67$ , Wald  $z = -3.46$ ,  $p < .001$ ). In contrast, for retained children Slope 2 was 23.69 points smaller than Slope 1 for retained children ( $s2_R - s1_R = -23.69$ ). These results show that for WJ reading grade score, retained children showed more reduction in slope from the short term to the longer term than did promoted children (see Figure 1D).

In the matched sample, there were children in the promoted group ( $n = 19$ ) who were subsequently retained in second or third grade; none of the children in the retained group were retained a second time. These results highlight the relatively high likelihood of subsequent retention for socially promoted children before the end of Grade 3 when state-mandated testing occurs. To minimize

the possible influence of retention at a later time on the effect of retention in first grade on the growth of WJ scores, we ran the same growth curve analyses with 19 pairs deleted that included the children retained after second grade. The obtained results were very similar to those reported above, and the inferences were identical on the basis of both sets of results.

### Moderating Effects

The moderating effects of the potential moderators on Slope 1 and Slope 2 for WJ W and grade scores are summarized in Table 3. For ease of presentation, we used only Coding Scheme 1. A significant moderating effect indicates that the effect of retention on Slope 1 and Slope 2 varied across different levels on a moderator. Only two of the nine moderator variables interacted with retention to affect Slope 1 for WJ reading W score and WJ math and reading grade scores. None of the moderators showed a significant moderating effect for Slope 2 for any of the WJ scores. The interaction between peer-rated externalizing problems and grade retention had a positive effect on Slope 1 for WJ reading W score ( $\gamma_{130} = 5.60$ , Wald  $z = 2.08$ ,  $p = .02$ ), indicating that in the short term, the benefit of promotion relative to retention on the WJ reading W score was higher for the children with lower levels of externalizing problems than for those with higher levels of externalizing problems (see Figure 2). The interaction between teacher-rated home-school relationship and grade retention had a negative effect on Slope 1 for WJ grade standard scores for math ( $\gamma_{130} = -8.19$ , Wald  $z = 2.05$ ,  $p = .02$ ) and for reading ( $\gamma_{130} = -8.37$ , Wald  $z = 2.04$ ,  $p = .02$ ), indicating that in the first piece, the relative benefit of retention versus promotion on grade scores was greater for children with less positive home-school relationships. Figure 3 displays the moderating effect of home-school relationship for WJ math grade score, which is very similar to that for WJ reading grade score.

Table 3

*Moderating Effects on Slope 1 and Slope 2 for Each of the Four WJ-III Scores*

Moderator	Math W score		Reading W score		Math grade score		Reading grade score	
	Slope 1 ( $\gamma_{130}$ )	Slope 2 ( $\gamma_{230}$ )	Slope 1 ( $\gamma_{130}$ )	Slope 2 ( $\gamma_{230}$ )	Slope 1 ( $\gamma_{130}$ )	Slope 2 ( $\gamma_{230}$ )	Slope 1 ( $\gamma_{130}$ )	Slope 2 ( $\gamma_{230}$ )
Age at eligibility determination	-3.97 (4.46)	2.93 (2.26)	11.96 (7.53)	-2.94 (3.80)	-8.87 (5.18)	3.67 (2.62)	5.86 (5.52)	-0.32 (2.79)
Parent-rated conduct problems	0.63 (3.27)	1.89 (1.75)	10.46 (5.60)	5.18 (3.02)	-0.24 (3.73)	-0.42 (2.00)	6.99 (3.91)	1.25 (2.11)
Parent-rated hyperactivity	0.22 (2.90)	0.47 (1.52)	-2.25 (5.01)	0.53 (2.65)	-0.78 (3.32)	-0.37 (1.74)	-3.30 (3.51)	-0.83 (1.84)

*Note.* Standard errors are in parentheses. Moderating effects are indicated by the coefficients associated with the interaction between a certain moderator and retention status following grade 1 ( $\gamma_{130}$  for Slope 1 and  $\gamma_{230}$  for Slope 2; see Equations 4 and 5). WJ-III = Woodcock-Johnson III.

\*  $p < .05$ .

Figure 2. Estimated two-piece linear growth curves of WJ reading W score for retained and promoted children with different levels of peer-rated externalizing problems (PEXT). WJ = Woodcock-Johnson III.

## Discussion

In this study, we used two-piece linear growth curve models to examine the short-term and longer term effects of grade retention on the change of WJ math and reading W and grade scores across 4 years. Analyses were conducted with retained and promoted children who were closely matched using modern propensity-matching procedures. One indicator of success of the propensity-matching procedure is the lack of initial differences in achievement between the retained and promoted children (see also Table 1).

### W Scores

For W scores, grade retention decreased the growth rate in the first piece (short term), but had either no significant effect on the growth rate (math) or increased the growth rate (reading) in the second piece (longer term). Thus, retained children grew more slowly in reading in the repeat year than did matched promoted children but “caught up” to the promoted children in the longer term. In the longer term, they grew in reading at a faster rate than did their matched promoted peers such that by Time 4 (when retained children were in third grade and most promoted children were in fourth grade), retained and promoted children did not differ significantly in reading ability.<sup>3</sup> Although it is tempting to extrapolate the linear growth for Slope 2 beyond Time 4, such extrapolation would be risky for related statistical and substantive reasons. Statistically, given the limited number of measurement waves collected so far in the present study, we were not able to fit nonlinear models of longer term growth. It is likely that longer term change will approach an asymptote over time so that linear growth only provides an approximation of the true form of growth over the 4-year period that was studied. Extrapolation beyond the range of the data from models that are only approximate is risky (Cook, 1993; MacCallum, 2003). Substantively, there is a rather abrupt change in the nature of reading and reading instruction that occurs between Grades 3 and 4 (Chall, 1996; Duke & Pearson, 2002). As retained children make this transition, their growth may slow. For math, the faster growth for promoted children in the short term

disappears in the longer term when retained and promoted children’s rate of growth is equivalent. However, the early disadvantage of retention on math growth is not compensated by more rapid growth in the longer term.

### Grade Standard Scores

In contrast to results for W scores, grade retention increased the growth rates of both the WJ math and reading grade standard scores in the short term but decreased growth rate of both scores in the longer term. Whereas promoted children showed only a slight decrease in their rate of growth in math and a somewhat larger decrease in their rate of growth in reading, retained children showed large drops in their growth rate from the first piece to the second piece for both the math and the reading grade standard scores. Thus, children did benefit from grade retention in the short term in terms of their performance relative to national grade norms. Previously published research on this sample at the end of Measurement Wave 2 found that retained students were rated by their classroom teacher as achieving more in the classroom than did their low-achieving promoted peers (Gleason, Kwok, & Hughes, 2007). The current findings suggest that this benefit erodes as retained students encounter an unfamiliar and more challenging curriculum. Again, additional waves of data are needed to determine whether the short-term benefits of retention on grade standard scores evaporate or reverse with additional years postretention.<sup>4</sup> Of particular concern is the impact of the sequence of failure, success, and failure that retained children appear to experience in their first 4 years of formal schooling on their academic self-efficacy and beliefs regarding the degree to which they can control academic outcomes. In future studies, we will investigate whether the documented association between grade retention and school withdrawal is mediated, in part, by the effect of grade retention on such academic-related beliefs.

### Moderators

We investigated nine potential moderators in a total of 72 tests (9 moderators  $\times$  4 achievement outcomes  $\times$  2 pieces). By chance alone, 3.6 tests would be expected to be statistically significant at an alpha of less than .05. Thus, the three significant results obtained should be interpreted as preliminary and requiring replication. As expected, the relative short-term benefit of promotion versus retention on growth in reading ability was greater for children with lower levels of peer-rated externalizing problems. This finding is consistent with the view that children with few behavioral problems (and greater prosocial skills) may be better

<sup>3</sup> Difference =  $-1.50$ , Wald  $z = -0.51$ ,  $p = .31$ .

<sup>4</sup> This study makes comparisons across grades on the basis of extensive normative data underlying the Woodcock-Johnson III grade standard scores. At this point in the longitudinal study, direct comparison of the trajectories of the retained and promoted groups (same-grade comparison) is not possible in the two-piece growth model that we used. Such a comparison would require discarding the measurement taken in the repeated year for the retained participants. Such a procedure would leave us with only two waves of postretention measurement (second grade and third grade) on which to compare the two groups. At least three postretention measurements are required to estimate the two-piece model of growth.

Figure 3. Estimated two-piece linear growth curves of WJ math grade score for retained and promoted children with different levels of home-school relationship (HSR). WJ = Woodcock-Johnson III.

prepared to meet the challenges of a more challenging curriculum. Similarly, the relative short-term benefit of retention versus promotion on growth in grade standard scores is greater for children who do not have strong parent involvement in their education. The limited number of significant interactions between retention and the moderator variables obtained in this study does suggest that the effects of retention are robust across a range of individual differences. An alternative explanation, of course, is that we failed to select the most appropriate variables for our tests of moderation.

### Strengths and Limitations of the Present Study

In contrast to many of the previous investigations of grade retention, this investigation drew on several recent advances in the design and analysis of observational studies that can greatly strengthen causal inferences (see West & Thoenes, 2008, for a review). First, we selected a large sample of children at risk for retention before the retention decision. This feature was expected to reduce, but not eliminate, baseline differences between retained and promoted children. It maximized the overlap between the promoted and the retained groups, eliminating the need to use statistical adjustment methods that may involve extrapolation. Second, we used an extensive battery of 72 pretest measures that were expected to be related to retention, math and reading achievement scores, or both. These measures were used to create propensity scores that were used to optimally match the retained and nonretained children before retention. Rosenbaum and Rubin (1983; see also Rosenbaum, 2002) showed analytically that propensity score methods provide a device that properly equates groups in observational studies if all of the important variables have been measured and balance on the variables is achieved between the treatment and control groups. Our selection of 72 baseline variables based on current theory and research represented a thorough attempt to measure all important baseline variables. As shown in Table 1, remaining differences between the groups after matching on propensity scores were minimal and nonsignificant. Third, we conducted growth curve modeling of the

WJ achievement scores that are scaled by means of the Rasch model. Rasch model scaling yields interval-level measurements on a single dimension. The use of the WJ measures that are not part of school district or state education assessments prevents teachers from "teaching to the test." Growth modeling permitted comparison of the slopes of the retained and promoted groups, both in the short term and in the longer term. This method represents an alternative strategy of comparing the groups. The combination of the use of two distinct methods, propensity scores and growth modeling, gave us two chances to get the adjustment for preexisting group differences right, giving us far greater confidence although not certainty in the causal interpretation of the effects of grade retention in the present study.

The primary limitations of the present study result are associated with the collection of only four waves of data to date. First, the number of waves of data restricts the forms of growth that could be investigated. We were able to investigate both short- and longer term growth in both WJ W scores and WJ grade standard scores. However, with only four waves of observation, our modeling was limited to the examination of linear effects. Other possible nonlinear models, such as the effects of grade retention increasing or decreasing over time to an asymptote, could not be investigated. We are currently collecting additional waves of data that will permit examination of such nonlinear effects. Second, additional waves of data collection will also permit a direct comparison between matched retained and promoted children when they are in the same grade. Same-grade comparisons involve examining the mean achievement of retained and promoted students when they are in the same grade, but not in the same year. Thus, the measurement of achievement for the retained children typically lags 1 year behind that for the promoted peers. Such direct grade comparisons are important because educators and parents may be more concerned with how retained students perform relative to their current classmates and grade expectations than to their former classmates, who are in a different grade (Lorenz, 2006).

In summary, the picture is complicated. Results differ on the basis of the scale used (age or grade), time elapsed since retention year, and achievement domain (reading vs. math). These results suggest that the question "What is the effect of grade retention on achievement?" is inappropriate. The more appropriate question is "What is the effect of grade retention, for whom, on what academic competencies, in reference to what standard (age or grade), at what point in time postretention?" With additional waves of data, we hope to provide a more complete picture of the effects of retention on achievement over time.

# Classroom Age Composition and Developmental Change in 70 Urban Preschool Classrooms

Arlen C. Moller

Children's Institute, Inc. and Gettysburg College

Emma Forbes-Jones and A. Dirk Hightower

Children's Institute, Inc. and University of Rochester

A multilevel modeling approach was used to investigate the influence of age composition in 70 urban preschool classrooms. A series of hierarchical linear models demonstrated that greater variance in classroom age composition was negatively related to development on the Child Observation Record (COR) Cognitive, Motor, and Social subscales. This was true when controlling for class size, general classroom quality, and socioeconomic status at the classroom level and for age, gender, and baseline ability at the child level. Additionally, to address possible concerns related to nonrandom assignment to classrooms, a series of models were run including variance in developmental age (i.e., baseline ability) at the classroom level and at the child level. The results were consistent for chronological age composition and developmental age composition at the classroom level; greater variance in classroom developmental age composition was negatively related to Time 2 scores on the COR Cognitive, Motor, and Social subscales. Furthermore, a cross-level interaction indicated that negative influence of greater variance in classroom developmental age composition was stronger for children older in developmental age. Implications for early childhood education policy are discussed.

**Keywords:** preschool, mixed age, single age, age composition, Child Observation Record

There is a great deal of variability in the age composition of U.S. preschool classrooms. Some preschool programs tightly restrict the range of ages in their classrooms (e.g., 3-year-olds only). Other programs permit, and in some cases even promote, a wide range of ages in the same classroom (e.g., from 2.5 years to as old as 5 years). Such variability in practice follows from a lack of consensus in both the theoretical and the empirical literature on the effects of age composition of classrooms on individual learning.

Research on the effects of classroom age composition on individual growth is not new. The theoretical writings of two pioneers in the field of early childhood development, Vygotsky and Piaget, are at odds with respect to the predicted impact of exposure of individual children to peers of variant ages on cognitive and social development (Bailey, Burchinal, & McWilliams, 1993; Hartup, 1993; Piaget, 1932; Rubin, Bukowski, & Parker 1998; Vygotsky,

1930/1978). From one perspective, that of Piaget (1932) and others, interacting with peers who are close in age is preferable. Children close in age are also likely to be more closely matched in terms of knowledge, skill, and power. As a result, children in such a setting are able to engage in and resolve cognitive and social conflicts with each other and play a variety of roles in their resolution. By contrast, Vygotsky and others argued that interaction with older, more competent children provides an optimal context for cognitive and behavioral development (Vygotsky, 1930/1978).

Interestingly, in the years since, relatively little empirical consensus has emerged. Yet despite a lack of consensus, the National Association for the Education of Young Children has given mixed-age classrooms its endorsement<sup>1</sup> (Bredekamp, 1987), in line with several researchers in the field (e.g., Katz, Evangelou, & Hartman, 1990; Whaley & Kantor, 1992). We now explore the extant literature relating to preschool classroom age composition more closely.

## Support for Mixed-Age Preschool Classrooms

Proponents of mixed-age preschool classrooms typically focus on the age-specific benefits most relevant to the younger children in such groupings. For example, as already noted, Vygotsky (1930/1978) spoke of the (perhaps) optimal challenges inherent in classroom contexts that include children who are older and thus more mature. Similarly, social learning theorists have maintained that

---

<sup>1</sup> The National Association for the Education of Young Children's (1996) most recent position statement does not take a position with regard to the age composition of preschool classrooms, and the recommendation for mixed-age classrooms extended by Bredekamp (1987) has not been retracted.

younger children benefit from being exposed to and modeling the behavior of older children (Bandura, 1986). In support, Rothstein-Fisch and Howes (1988) found that when toddlers interacted with slightly older peers, the younger children exhibited more complex language and engaged in more complex play in a family childcare setting. Howes and Farver (1987) similarly found that toddlers whose play partners were older peers engaged in more complex social play.

Other advocates for mixed-age classrooms have posited that older children, too, may benefit from exposure to younger children (Katz et al., 1990; Lloyd, 1999). For example, in such settings older children are in a position to more readily practice prosocial behavior (Derscheid, 1997; Urberg & Kaplan, 1986) and leadership skills (French, Waas, Stright, & Baker, 1986), given their elevated status in mixed-age group interactions. Chapman (1994) found that older children in a mixed-age elementary school setting served as mentors for younger children both spontaneously and when asked. Although the specific benefits that have been linked to mixed-age peer interaction have thus far been age specific (i.e., only relevant to younger or older children), advocates of mixed-age classrooms maintain that the age-specific advantages are presumably passed on as a child progresses through such a program (i.e., younger children will one day be older children in the same classroom), and thus an egalitarian ethic is preserved.

Further research has suggested additional benefits of mixed-age classrooms for all children, regardless of age. For example, research by Goldman (1981) has suggested that both 3- and 4-year-olds in mixed-age preschool classrooms engaged in significantly less parallel (as opposed to interactive) forms of play, relative to those in same-age classrooms. An investigation by Urberg and Kaplan (1986) found that both older and younger children in mixed-age preschool classrooms exhibited greater interactive functional play and less parallel functional play, relative to those in same-age classrooms. Rubin, Maioni, and Hornung (1976) have argued that interactive play represents a more mature level of play, relative to parallel play. Thus, these authors argued that mixed-age classrooms facilitate more mature play and therefore more optimal social-cognitive development.

Whaley and Kantor (1992) suggested that mixed-age classrooms may help to lessen the likelihood of parents and caregivers to make comparisons among children in terms of development. Instead, mixed-age rooms allow parents to focus on each child's development as an individual. As such, mixed-age classrooms may decrease competition between peers, focusing children instead on more mastery-oriented goals. Many studies conducted with children, adolescents, and college students confirm that focusing on individual standards (i.e., mastery goals) is optimal in terms of maintaining both intrinsic motivation and achievement in the classroom (see Elliot & Dweck, 2005, and Nicholls, 1989, for reviews). Blasco, Bailey, and Burchinal (1993) found that children with developmental disabilities, in particular, were more likely to engage in mastery play when they were enrolled in mixed-age settings.

Whaley and Kantor (1992) further speculated that benefits extend to both children and teachers as a result of the "family climate" and continuity of care fostered by mixed-age classrooms. That is, these authors suggested that the abrupt transitions in climate encountered when moving between restricted-age classrooms at larger childcare facilities could be stressful for both the

teachers and the children. However, an empirical investigation into the perceived stress levels of children and teachers in such facilities has yet to be published.

Several authors have noted that gender segregation is less prevalent in mixed-age classrooms relative to restricted-age settings (Field, 1982; Lougee, Grueneich, & Hartup, 1977; Roopnarine et al., 1992; Roopnarine & Johnson, 1984). It seems that in mixed-age contexts, age plays a more powerful role than gender in peer playmate selection. Thus, at a society level, long-term promotion of gender equality might be better served by more preschools moving toward a greater diversity in terms of classroom age composition. Such an argument is highly speculative, as no empirical explorations into a relation between preschool classroom age composition and attitudes related to gender equality have been conducted.

Finally, some research has supported the notion that mixed-age peer interactions occur naturally, outside the classroom context (Ellis, Rogoff, & Cromer, 1981). An observational study by Ellis et al. (1981) of 436 children ages 1–2 found that target children were with same-age peers in only 6% of the observations recorded, compared with 55% of the observations involving mixed-age peer interactions (with children who differed in age by at least 1 year). These findings related to naturalistic social interactions, however, are inconclusive to the extent that this may be because of peer accessibility or children actively seeking out companionship from mixed-age peers. Goldman's (1981) research on mixed- versus same-age preschool classrooms demonstrated that—within mixed-age classrooms—age did not significantly influence choice of playmates. Thus, some authors have suggested that children are naturally better suited to developing in the context of mixed-age groups (Ellis et al., 1981; Whaley & Kantor, 1992).

### Support for Restricted-Age Preschool Classrooms

The central argument in favor of restricting the range of age in preschool classrooms concerns a desire to provide each child with an optimal degree of challenge and the utility of specialization toward meeting this goal. As such, a criticism that has been levied against mixed-age classrooms in favor of more restricted-age preschool groupings concerns the development of age-appropriate curriculum and staff training. Specifically, when teacher training and curriculum are uniquely focused on what is developmentally appropriate for a more restricted age range of children, the quality of the classroom climate will be higher.

Although some authors have maintained that mixed-aged classrooms facilitate more mature forms of play (Goldman, 1981; Howes & Farver, 1987; Rothstein-Fisch & Howes, 1998; Urberg & Kaplan, 1986), other researchers have found evidence to the contrary or suggestive of a more complex effect than is often highlighted. For example, Roopnarine et al. (1992) observed more social and nonsocial dramatic play in preschoolers attending same-age relative to mixed-age classrooms, whereas more social-constructive and nonsocial manipulative play was seen in mixed-age classrooms. Roopnarine et al. maintained that dramatic play was the more complex form of play relative to manipulative play, suggesting that same-age classrooms facilitated more sophisticated play behaviors. Urberg and Kaplan (1986) reported finding a greater incidence of interactive, mature forms of play in mixed-age preschool classrooms relative to same-age classrooms; however,

these authors also reported several observed costs associated with mixed-age classrooms. For instance, younger children in mixed-age classrooms tended to be involved in a greater number of negative interactions. This was attributed to the potential for frustration in older children resulting from interactions with less mature younger children. Furthermore, Urberg and Kaplan found that older children in mixed-age classrooms were more likely to be onlookers, detaching themselves from social interaction. Similarly, Goldman (1981) found more solitary play and less participation in teacher-directed activities among older children in mixed-age classrooms. Urberg and Kaplan speculated that teachers in the mixed-age classrooms might have had a more difficult time providing a sufficient variety of activities suitable for keeping children of varied age and ability interested and involved.

Proponents of mixed-age classrooms often focus on benefits to younger children, but the potential costs to the older children in such classrooms may sometimes be overlooked. A study of mixed-age elementary school classrooms (children ages 6 to 9 years) by Byrnes, Shuster, and Jones (1994) confirmed that both older students and their parents rated the quality of the academics in multiage classrooms less positively than that in single-age classrooms. Despite failing to report any benefits found for older, more able students in their study, the authors suggest that administrators ought to pay special attention to helping "more able students in seeing how they benefit from being in multiage classrooms" (p. 21). In another observational investigation of play behavior in different classrooms, Dunn, Kontos, and Potter (1996) monitored family childcare homes and found that frequency of interactions with older peers were associated with more complex cognitive play, whereas interactions with younger and same-age peers were associated with less complex social and cognitive play and lower receptive language scores. One lab experiment (Tudge, 1992) compared mixed- versus matched-competence peers (ages 5–9 years) working in dyads. The results of this experiment suggested that regression in thinking was as likely a consequence of mixed groupings as was improvement. These results suggest that at least with regard to some cognitive outcomes, older children in mixed-age groups may suffer. Furthermore, support for such a hypothesis was found by Winsler et al. (2002). Winsler et al. studied longitudinally one preschool's transition from two single-age classrooms (separate 3- and 4-year-olds) to two mixed-age classrooms (combined 3- and 4-year-olds). In this study, statistical interactions were found between child age and classroom age composition in predicting task focus in the classroom. Although 3-year-olds seemed to do better after the change to mixed-age classrooms, 4-year-olds were observed to be less focused and goal directed. Moreover, children of both ages were observed demonstrating significantly more overt positive affect (e.g., smiles and laughter) and less neutral affect in the single-age classrooms compared with the mixed-aged classrooms.

The 1995 meta-analysis conducted by Veenman concluded that there were no academic or social differences between elementary school children attending mixed-age and same-age classrooms. Similarly, Blasco et al. (1993) reported no differences in terms of complex mastery play in same- versus mixed-age classrooms when their observations focused on typically developing preschool-age children; the benefits attributed to mixed-age classrooms and reported above were (again) specific to children with developmental disabilities.

## Ability-Based Groupings

As noted, many of the theoretical assertions for or against mixed- and restricted-age groupings are based on the assumption that age is closely related to ability. By this token, ability-based groupings may be expected to have an influence on developmental outcomes similar to that of age-based groupings. Mirroring the literature supporting the efficacy of mixed-age classrooms, many researchers have championed mixed-ability groupings in terms of benefits to be reaped by disadvantaged children who are lower in ability (Guralnick, 1981; Rogers & Ross, 1986; Tach & Fargas, 2006). For example, Tach and Fargas (2006) found that within kindergarten and first-grade classrooms in which ability-based groupings were used, placement into a higher ability group exerted a uniformly positive effect on student learning-related behavior and reading achievement. Typically, these studies have implicitly assumed that the costs for higher ability children in such mixed-ability groupings are negligible, although several exceptions (e.g., Guralnick, 1981) have reported no detrimental impact on higher ability children in mixed-ability groupings. Nevertheless, a theme that runs through these studies advocating for mixed-ability groupings is that an important and focal goal is ensuring that the needs of students who have experienced situations that place them at risk or are disadvantageous for their academic development are met. From an entirely different perspective, some researchers have advocated expressly for the interests of the most gifted and talented children. Researchers focused on those children higher in ability tend to advocate for more restricted-ability groupings, such that high-ability children have more opportunities to interact with peers of similar ability (e.g., Gallagher, 1986). To summarize, as is the case in the literature focused on age-related groupings, the literature on ability-related groupings is mixed; furthermore, the most controversial aspect of the debate concerns those children in mixed contexts who are older, higher in ability, or both.

## Shortcomings of the Extant Literature Addressed by the Present Investigation

Many of the studies that have expressly focused on classroom age composition have targeted an elementary school population, which makes it difficult to extend the conclusions to preschool classrooms (e.g., Chapman, 1994; French et al., 1986; Veenman, 1995). Early childhood (ages 2 to 5) is a period of relatively rapid development; thus, the impact of age differences in classroom composition within this range is likely to be magnified, if not distinctly different, in preschool classrooms relative to that found in elementary school settings among older children.

Furthermore, as Winsler et al. (2002, p. 306) pointed out, "most of the (extant) research exploring the effects of age-composition on children's peer interactions has been conducted in laboratory or quasi-laboratory settings." In other words, with few exceptions, the extant literature lacks empirical research on preschool classroom age composition conducted in preschool classrooms. The exceptions (Bailey et al., 1993; Goldman, 1981; Winsler et al., 2002) have been limited to research conducted with a relatively small number of classrooms, typically restricted to a single organization. For example, Bailey et al.'s (1993) investigation tracked the developmental trajectories of just 59 children between the ages of 21 and 67 months. Goldman's (1981) sample consisted of just three

classrooms, and Winsler et al.'s (2002) sample included only four. Furthermore, the samples included in the vast majority of studies reviewed above came from affluent or middle-class suburban communities. From the perspective of triage at the level of public policy, an argument could be made for focusing attention first on the neediest and most underserved populations. Yet, urban samples of lower socioeconomic standing have typically been ignored in this literature. An additional limitation of the extant literature is that researchers have typically focused on a limited range of outcomes, perhaps masking a richer, more ambiguous phenomenon.

We undertook an investigation into the question of preschool classroom age composition on a scale far larger than previously conducted (806 children in 70 classrooms), a sample that included every preschool classroom under the administrative umbrella of a public school district in a mid-sized city (approximate population = 212,000). We included as outcomes in our research well-validated measures of various aspects of development (cognitive, social, and motor) and controlled for baseline levels on entering the classroom. Furthermore, we assessed and controlled for general classroom quality. As a result, this research should offer fresh and rich insight into questions concerning the consequences of preschool classroom age composition that can be extended more easily to urban populations.

## Method

### *Participants*

Participants included 806 preschool children from 70 preschool classrooms. The classrooms in the sample all fell under the administrative umbrella of a public school district in a mid-sized city in the northeastern United States. The mean age of children in the sample at Time 1 was 4.15 years ( $SD = 0.50$ ; 51% male). The ethnic composition included 57% African American, 17% White, 15% Hispanic, 2% Asian, and 9% children of unreported race or ethnicity. Overall, the students enrolled in the district were low in socioeconomic status (SES). Across the district, 86% of students came from homes below the poverty line, and 84% of the students qualified for free or reduced-price lunch. The mean number of students in a classroom was 16.34 (range = 8 to 21). The mean difference in age between the oldest and youngest child in a classroom was 1.58 years (range = 0.73 to 2.73). The mean standard deviation of children's age in classrooms was 0.44 (range = 0.10 to 0.70).

### *Measures*

#### *Child Observation Record (COR)*

This instrument (High/Scope Educational Research Foundation, 1992) measures several relevant domains of preschool children's development. The COR includes 32 items, with response options ranging from *least developed* to *most developed* on a 5-point scale, to be filled out by teachers immersed in the classroom environment from observations of naturally occurring behaviors. Before teachers used the COR they received 3 hr of training familiarizing them with this instrument. A recent investigation, focused on validating the COR, found that a three-factor solution, which included Cognitive Skills, Social Engagement, and Coordinated Movement/Motor Skills, best accounted for the correlations among the 32

COR items (Fantuzzo, Hightower, Grim, & Montes, 2002). Thus, in the present investigation, we used this three-factor solution, as well as the total COR (a combined score across all three subscales). Convergent and divergent validity studies have found significant relations between COR dimensions and other classroom competency constructs, such as peer play interactions (Penn Interactive Peer Play Scale; Fantuzzo, Coolahan, Mendez, McDermott, & Sutton-Smith, 1998; Fantuzzo et al., 2002; McWayne, Fantuzzo, & McDermott, 2004; Sekino & Fantuzzo, 2005), psychological adjustment (Teacher-Child Rating Scales [Fantuzzo et al., 2002; Perkins & Hightower, 1999, 2000] and Adjustment Scales for Preschool Intervention [Lutz, 1999; Lutz, Fantuzzo, & McDermott, 2002; Sekino & Fantuzzo, 2005]), receptive vocabulary (Peabody Picture Vocabulary Test-III; Dunn & Dunn, 1997; Fantuzzo et al., 2002), general learning skills (Preschool Learning Behaviors Scale [McDermott, Green, Francis, & Stott, 1996; McWayne et al., 2004; Sekino & Fantuzzo, 2005] and McCarthy Scale of Children's Abilities [McCarthy, 1972; Schweinhart, McNair, Barnes, & Lerner, 1993]), early reading ability (Test of Early Reading Ability, 3rd ed.; Reid, Hreski, & Hammill, 2001; Sekino & Fantuzzo, 2005), early math ability (Test of Early Mathematics Ability, 2nd ed.; Ginsburg & Broody, 1990; Sekino & Fantuzzo, 2005), kindergarten literacy (Dynamic Indicators of Basic Early Literacy Skills; Good & Kaminski, 2002; Sekino & Fantuzzo, 2005), and kindergarten academic success (Early Screening Inventory—Revised Kindergarten Version; Meisels, Marsden, Wiske, & Henderson, 1997; McWayne et al., 2004).

#### *Early Childhood Environment Rating Scale—Revised (ECERS-R)*

The ECERS-R is among the most widely used observational tools allowing for objective assessment of preschool classroom quality (Henry et al., 2004; Howes & Smith, 1995; Scarr, Eisenberg, & Deater-Deckard, 1994). The seven areas of classroom quality that the ECERS-R measures are space and furnishing, personal care routines, language and reasoning, activities, interaction, program structure, and parents and staff. Each area contains 5–10 items that represent various elements of that area. For the present investigation, we averaged scores across all seven areas to create an overall, composite measure of classroom quality.

### *Procedure*

Seventy teachers completed the COR for each child in their classroom, once in the fall and again in the spring. Teachers participated as part of an ongoing community assessment partnership that was open to all providers of services to preschool children in the area. Teachers were trained on the COR according to High/Scope standards, including procedures for observation and note taking, before completion of COR protocols. Trainees matched observations of videotaped classrooms against a standard to establish reliability levels of at least 80%. Master teachers and consultants were available to any teacher who had any questions or issues after the initial training for the entire school year. After COR ratings were completed, the first round of data sheets were returned to us for processing in October; the second round of data sheets were returned to us for processing in late April. Thus, the

typical length of time between COR assessments was 6–7 months. COR ratings were returned for 95% of the original sample.<sup>2</sup>

ECERS–R observations of classroom quality were conducted by 24 observers midway through the academic year (in the months of February, March, and April). For classroom observers in their 1st year of training, ECERS–R observers attended a 15-hr training program and reached an interrater reliability of 85% agreement with a master observer who was trained by the ECERS–R authors. For observers in their 2nd year, an additional 4–5 hr of training were required. All observers maintained an interrater reliability of 80% agreement, with 20% of their observations being checked.

## Results

### COR Scoring

We calculated COR scores for each of the three subscales—Cognitive Skills (Time 1 [T1],  $\alpha = .92$ ; Time 2 [T2],  $\alpha = .91$ ), Social Engagement (T1,  $\alpha = .93$ ; T2,  $\alpha = .93$ ), and Coordinated Movement/Motor (T1,  $\alpha = .87$ ; T2,  $\alpha = .90$ )—and the Combined/Total COR (T1,  $\alpha = .96$ ; T2,  $\alpha = .96$ ). The range for each COR subscale was from 0 to 5. Mean COR scores and standard deviations at Time 1 were, for Cognitive Skills, 2.08 and 0.69, respectively; for Social Engagement, 2.63 and 0.75, respectively; for Coordinated Movement/Motor, 2.68 and 0.68, respectively; and for Total COR, 2.43 and 0.66, respectively. Mean COR scores and standard deviations at Time 2 were, for Cognitive Skills, 3.07 and 0.77, respectively; for Social Engagement, 3.72 and 0.80, respectively; for Coordinated Movement/Motor, 3.65 and 0.80, respectively; and for Total COR, 3.48 and 0.72, respectively. Intercorrelations among the three COR factors ranged from .78 to .80 at Time 1 and from .71 to .76 at Time 2 (see Table 1). The high degree of correlation among the three COR factors indicates that analyzing each factor and the total COR score is justified.

### Primary Analysis

We used hierarchical linear modeling (HLM; Bryk & Raudenbush, 1992) for our primary tests. HLM appropriately addresses the hierarchically nested design of our data set, in which lower level units, children, were nested within a higher level unit, classroom. HLM treats classroom as a random rather than a fixed effect, thereby permitting generalizations of the findings to a wider population. Unlike regression models, this analysis allows for the possibility that the within-group (i.e., classroom) slopes may differ significantly from one classroom to another. Such an approach

makes it possible to see whether the relationship between child's age and change in COR score differs from classroom to classroom. For example, a positive main effect for classroom age range would imply that classrooms that are more mixed in terms of age composition are related to greater developmental growth, as assessed by COR change.

We calculated intraclass correlation coefficients (ICCs) for each of the four difference outcomes variables from the unconditional models: total COR score,  $ICC = .25$ ,  $\chi^2(69, N = 70) = 329.30$ ,  $p < .001$ ; COR Social,  $ICC = .25$ ,  $\chi^2(69, N = 70) = 330.56$ ,  $p < .001$ ; COR Motor,  $ICC = .23$ ,  $\chi^2(69, N = 70) = 301.19$ ,  $p < .001$ ; and COR Cognitive,  $ICC = .25$ ,  $\chi^2(69, N = 70) = 333.65$ ,  $p < .001$ . These findings confirmed that a HLM approach would provide substantial benefits over a standard fixed-effects model approach for the analysis of these data.

### Models 1–8: Chronological Age Effects

In the first set of models run, the primary classroom-level (Level 2) predictor was classroom chronological age composition, which was operationalized in two ways: (a) the range in chronological age between the youngest and oldest child in a given classroom and (b) the standard deviation of chronological age within a given classroom. Covariate predictors entered at the classroom level included the number of students in the classroom ( $M = 16.34$ ). At the person or child level (Level 1), child's chronological age at Time 1, gender, and COR assessment score at Time 1 were included as predictors. HLM estimates classroom-level and child-level effects simultaneously. Thus, classroom-level effects are statistically independent of child-level effects. All predictors (both classroom and child level) were centered on the sample (grand) means. The multi-level equations used for this basic model are described in Appendix A. This basic model was run independently using two different indicators of classroom chronological age composition (chronological age range in classroom and standard deviation of chronological ages in classroom) and four different outcomes (total COR score and each subscale from the COR), resulting in Models 1–8.

*Chronological age and the composite total COR.* The first version run of the basic model described above included chronological age range as the index of classroom chronological age composition and total COR score at Time 2 as the outcome measure (Model 1). The results of this hierarchical linear model are summarized in Table 2. Overall, there was a significantly negative main effect at the classroom level for classroom chronological age composition ( $\gamma_{01} = -.19$ ,  $p < .05$ ), and a nonsignificant effect for class size ( $\gamma_{02} = .02$ ,  $p = .37$ ). As expected, there were significant main effects observed at the child level for child's chronological age ( $\gamma_{10} = .23$ ,  $p < .001$ ) and Time 1 total COR score ( $\gamma_{20} = .83$ ,  $p < .001$ ). There was also a significant main effect at the child level for gender ( $\gamma_{30} = .06$ ,  $p < .05$ ), such that girls scored higher than boys on the COR at Time 2, controlling for

Table 1  
Correlations Between the Three COR Factors at Time 1 and Time 2 ( $N = 806$ )

Factor	1	2	3	4	5	6
1. T1 Social	—					
2. T1 Cognitive	.78**	—				
3. T1 Motor	.79**	.80**	—			
4. T2 Social	.60**	.50**	.52**	—		
5. T2 Cognitive	.57**	.63**	.55**	.71**	—	
6. T2 Motor	.52**	.52**	.58**	.75**	.76**	—

\*\* $p < .01$ .

<sup>2</sup> Forty-two children were dropped from the study (roughly 5%) because Time 2 COR scores were not available. These 42 children did not differ significantly from the retained sample ( $n = 806$ ) in terms of mean age, racial, or gender distribution.

Table 2  
Fixed Effects for Models 1–4 (Classroom Age Range as Focal Level 2 Predictor)

Parameter	Model 1: Total COR		Model 2: COR social		Model 3: COR motor		Model 4: COR cognitive	
	Coeff	SE	Coeff	SE	Coeff	SE	Coeff	SE
Average classroom intercept ( $\gamma_{00}$ )	3.53***	0.04	3.75***	0.05	3.67***	0.04	3.12***	0.04
Age range ( $\gamma_{01}$ )	−0.19*	0.10	−0.22†	0.11	−0.16†	0.09	−0.19*	0.09
Class size ( $\gamma_{02}$ )	0.02	0.02	0.02	0.02	0.02	0.02	0.01	0.02
Intercept for child's age ( $\gamma_{10}$ )	0.23***	0.05	0.20***	0.05	0.31***	0.05	0.33***	0.06
Age range × Child's age ( $\gamma_{11}$ )	−0.10	0.08	−0.04	0.09	−0.08	0.10	−0.12	0.11
Intercept for T1 total COR ( $\gamma_{20}$ )	0.83***	0.04	0.72***	0.04	0.73***	0.05	0.76***	0.05
Intercept for child's gender ( $\gamma_{30}$ )	0.06*	0.03	0.09**	0.03	0.09*	0.04*	0.03	0.03

Note. Model 1 = Total COR as dependent outcome; Model 2 = COR Social as dependent outcome; Model 3 = COR Motor as dependent outcome; Model 4 = COR Cognitive as dependent outcome; COR = Child Observation Record; Coeff = coefficient; T1 = Time 1.

\* $p < .05$ . \*\* $p < .01$ . \*\*\* $p < .001$ . † $p < .10$ .

Time 1 score. Finally, the cross-level interaction between classroom chronological age composition and child's chronological age was nonsignificant ( $\gamma_{11} = -.10, p = .23$ ). This nonsignificant cross-level interaction suggested that the negative classroom-level main effect for chronological age composition was not moderated by the child-level chronological age of children in these classrooms.

The total variance at Level 1 (total COR at Time 2) was 1,648.63. This was estimated by specifying an unconditional model that included only a random intercept for each classroom. The error variance unaccounted for by the conditional Model 1 was reduced to 984.81. Comparison of these results indicates that 40.26% of the variance in total COR at Time 2 was accounted for by Model 1.

*Chronological age and the three COR subscales: Social, Motor, and Cognitive.* Next, we ran three hierarchical linear models using age range as the index of classroom age composition, independently predicting the three subscales from the COR as outcomes: Social, Motor, and Cognitive (Models 2, 3, and 4, respectively). The estimates from each model are summarized in Table 2, and the observed pattern of results was remarkably consistent across all three COR subscales. The negative main effect for classroom chronological age range was marginally significant when predicting COR Social and COR Motor and significant when predicting COR Cognitive. Child's chronological age was a significant predictor of all three COR subscales, as were Time 1 scores (for each subscale, respectively). Child's gender was a significant predictor of COR Social and COR Motor (in each case, girls scored higher), but did not significantly predict COR Cognitive. The cross-level interaction between child's chronological age and classroom chronological age range was nonsignificant for all three COR subscales.

The total variance at Level 1 was estimated by specifying an unconditional model that included only a random intercept for each classroom for each of the three COR subscales: Social, 1,813.15; Motor, 1,825.91; and Cognitive, 1,755.37. The error variance unaccounted for by Model 2 was reduced to 1,291.08; thus, the model accounted for 28.79% of the variance. The error variance unaccounted for by Model 3 was reduced to 1,367.06; thus, the model accounted for 25.13% of the variance. The error variance unaccounted for by Model 4 was reduced to 1,179.26; thus, the model accounted for 32.82% of the variance.

Next, we reran the four models described above, substituting the standard deviation of chronological ages for chronological age range at the classroom level (Models 5–8). Standard deviation of chronological ages in classrooms represents an alternative index of classroom chronological age composition that is more resistant to extreme values (i.e., if a single child were much younger or older than all the other children in a classroom). The pattern of results replicated those found using chronological age range as the index of classroom chronological age composition. For a summary of these results, see Table 3.

The error variance unaccounted for by Model 5 was reduced from 1,648.63 to 978.51; thus, the model accounted for 40.65% of the variance. The error variance unaccounted for by Model 6 was reduced from 1,813.15 to 1,284.49; thus, the model accounted for 29.16% of the variance. The error variance unaccounted for by Model 7 was reduced from 1,825.91 to 1,361.85; thus, the model accounted for 25.42% of the variance. The error variance unaccounted for by Model 8 was reduced from 1,755.37 to 1,172.09; thus, the model accounted for 33.23% of the variance.

### Models 9–16: Developmental Age Effects

In the second set of models run, the primary classroom-level (Level 2) predictor was classroom developmental age composition. Developmental age was operationalized as COR score at Time 1. As such, in the interest of conceptual clarity, in the following models Time 1 COR score is referred to as *developmental age*. Developmental age range was operationalized in two ways: the range in score between the lowest and highest Time 1 COR score in a given classroom and the standard deviation of COR scores at Time 1 within a given classroom. Covariate predictors entered at the classroom level included the number of students in the classroom ( $M = 16.34$ ).

At the person or child level (Level 1), child's developmental age (i.e., Time 1 COR score), gender, and age at Time 1 were included as predictors. Finally, we included a term representing the cross-level interaction between child's developmental age (Time 1 COR) and classroom developmental age composition (range in COR scores or standard deviation of COR scores). HLM estimates classroom-level and child-level effects simultaneously. Thus, classroom-level effects are statistically independent of child-level

effects. All predictors (both classroom and child level) were centered on the sample (grand) means. The multilevel equations used for the second basic model are described in Appendix B. (As noted earlier, the multilevel equations used for the first basic model are described in Appendix A.) Paralleling Models 1–8, the second basic model was run independently, using two different indicators of classroom developmental age composition (developmental age range in classroom and standard deviation of developmental ages in classroom) and four different outcomes (total COR score and each subscale from the COR), resulting in Models 9–16.

*Developmental age and the composite COR total.* The basic model described above was first run using developmental age range as the index of classroom developmental age composition and total COR score at Time 2 as the outcome measure (Model 9). The results of this hierarchical linear model are summarized in Table 4. Overall, there was a significantly negative main effect at the classroom level for classroom developmental age range ( $\gamma_{01} = -.23$ ,  $p < .01$ ). The classroom-level effect for class size was nonsignificant ( $\gamma_{02} = .02$ ,  $p = .31$ ). As expected, there were significant main effects observed at the child level for child's developmental age ( $\gamma_{10} = .86$ ,  $p < .001$ ) and child's chronological age ( $\gamma_{20} = .22$ ,  $p < .001$ ). There was also a

significant child-level main effect for gender ( $\gamma_{30} = .06$ ,  $p < .05$ ). Finally, a significant cross-level interaction between classroom developmental age range and child's developmental age was observed ( $\gamma_{11} = -.17$ ,  $p < .01$ ). This cross-level interaction suggested that there was little difference in terms of Time 2 COR for children lower in developmental age (i.e., 1 standard deviation below the grand mean Time 1 Total COR score) in classrooms with mixed versus restricted developmental age ranges. However, for children higher in developmental age (i.e., 1 standard deviation above the grand mean Time 1 Total COR score), there was a significant advantage to being in a classroom with a restricted developmental age range versus a classroom with a wide range in developmental age. This interaction is illustrated in Figure 1.

The total variance at Level 1 (total COR at Time 2) was 1,648.63. This was estimated by specifying an unconditional model that included only a random intercept for each classroom. The error variance unaccounted for by the conditional Model 1 was reduced from 1,648.63 to 989.45; thus, the model accounted for 40.00% of the variance.

*Developmental age and the three COR subscales: Social, Motor, and Cognitive.* Next, three hierarchical linear models using developmental age range as the index of classroom developmental

Figure 1. Classroom developmental age range by child's developmental age predicting total Child Observation Record (COR) score at Time 2, controlling for total COR score at Time 1.

age composition were run independently, predicting the three COR subscales as outcomes: Social, Motor, and Cognitive (Models 10, 11, and 12, respectively). The estimates from each model are summarized in Table 4, and the observed pattern of results was remarkably consistent across all three COR subscales. Classroom-level developmental age range was a significantly negative predictor of all three subscales from the COR. Class size was not a significant predictor of any of the three COR subscales. Child's chronological age and developmental age significantly predicted all three COR subscales. Child's gender significantly predicted COR Social and COR Motor (girls scored higher), but not COR Cognitive. Finally, the cross-level interaction between classroom-level developmental age range and child's developmental age was significant only with regard to COR Social, but did not significantly predict COR Motor or COR Cognitive. These results are summarized in Table 4.

Next, we reran the four models described above, substituting the standard deviation of developmental ages as the indicator of developmental age composition at the classroom level (Models 13–16). Standard deviation of developmental ages in classrooms represents an alternative index of classroom developmental age composition that is more resistant to extreme values (i.e., if a single child scored much higher or lower on the Time 1 COR relative to all the other children in a given classroom). The pattern of results replicated those found using developmental age range as the index of classroom developmental age composition. These results are summarized in Table 5.

**Classroom quality.** We next included classroom quality (ECERS-R) in the models described above exploring the influence of both chronological (Models 1–8) and developmental (Models

9–16) age composition on residual COR change. The significant effects reported for classroom age composition all remained significant when controlling for classroom quality. That is, classroom-level variance in age, chronological or developmental, was negatively related to residual COR change. Furthermore, there were no significant main effects found for classroom quality and no significant classroom-level interactions between classroom quality and classroom age composition.

It is, however, worth noting that the ECERS-R scores for the classrooms in this sample were uniformly approaching ceiling levels for excellence. The maximum possible score for overall classroom quality on this scale is 7.0. In the school district sampled, the mean score for overall classroom quality was 6.42 ( $Mdn = 6.75$ ), with a standard deviation of only 0.77. Thus, the level of ECERS-R-rated classroom quality in this sample was greater than 2 standard deviations above the national average (approximately 5.0), as previously reported by Montes, Hightower, Brugger, and Moustafa (2005).

**SES.** Next, an indicator of classroom-level SES was included in the models (1–16) described above. In the absence of direct indicators of family income, we used mothers' level of education as an indirect indicator of child-level SES. Studies that have explored the relation between level of education and income typically report strong correlations (e.g.,  $r = .51$ ; Robert, 1998); researchers often use these variables as interchangeable indicators of SES in multivariate models owing to the high degree of shared variance (e.g., Winkleby, Kraemer, Ahn, & Varady, 1998). Thus, mean and median mothers' highest completed level of education were used as indicators of SES at the classroom level.<sup>3</sup> Across all 70 classrooms in the sample, the mean level of mothers' education was 3.25 ( $SD = 1.09$ ), corresponding to a level of education between high school diploma or GED and some college. The significant effects reported for classroom age composition all remained significant when controlling for classroom-level SES. That is, greater variance in age, chronological or developmental, at the classroom level was negatively related to residual COR change. Furthermore, no significant main effects were found for classroom SES, and there were no significant classroom-level interactions between classroom SES and classroom age composition.

## General Discussion

This investigation represents a unique and important contribution to the literature on preschool classroom age composition in a number of respects. First, the study included a sample far larger than that in any previously conducted research, 806 children from 70 different preschool classrooms. Second, this research is among the first to use a well-validated assessment of early childhood development (i.e., the COR) in a variety of domains (social, motor, and cognitive) and to include assessments at two time points (spaced approximately 6 months apart). Thus, we were able to explore the influence of classroom age composition on residualized change in various aspects of development. Additionally, important covariates, such as general classroom quality (i.e., the

<sup>3</sup> Mother's education was available for 88% of the children in the sample. To calculate mean and median mothers' education at the classroom level, missing values were replaced with the classroom (or group) mean.

ECERS-R) and SES, were included. Finally, this research focuses on a population (i.e., urban preschool children) that has been understudied, yet is extremely important from the perspective of policymakers and others interested in social welfare.

The results were surprising, insofar as they contradicted assertions made by advocates of mixed-age classrooms (Bredekamp, 1987; Katz et al., 1990), yet remarkably consistent across indicators of classroom age composition and domains of development. We consistently observed a significant main effect at the classroom level for classroom age composition, which suggested that a wide range in children's ages within a classroom (and high standard deviations in terms of age) was negatively related to development. This was true in terms of overall development (i.e., total COR score) and, independently, in terms of social, motor, and cognitive domains of development (COR subscales).

Furthermore, the negative relation observed between classroom (chronological) age composition and developmental outcomes was replicated using an indicator of classroom developmental age composition (range and standard deviation of Time 1 COR scores). This alternative approach to exploring the impact of classroom age composition was important for a number of reasons.

First, the parallel set of findings observed for classroom developmental age range helps to mitigate potential confounds that might have resulted from nonrandom assignment to classrooms. For example, one might imagine that the oldest children in mixed-age classrooms may be more likely to have been held back and that the brightest children are culled from these mixed-age classrooms when they become older. Those classrooms with wider distributions in age might also have a higher frequency of older children who are slow learners or are developmentally delayed. However, the models run using Time 1 COR scores as an indicator of developmental age help to address and dismiss the notion that older children in mixed-age classrooms in our sample were developmentally delayed or otherwise noncomparable to older children in single-age classrooms, as chronological age was separated from developmental age, and the pattern of results did not change.

Second, the fact that a wider distribution of both chronological and developmental age in preschool classrooms was negatively related to development, coupled with a large and diverse sample of classrooms, makes a strong case for generalizing this effect to other urban populations.

Third, the use of Time 1 COR scores as an indicator of developmental age allowed us to identify a cross-level interaction between classroom developmental age composition and child's developmental age, which further specifies the nature of the significant main effect found for classroom developmental age composition. This cross-level interaction suggested that children high in developmental age were most negatively influenced by assignment to classrooms with wider distributions of developmental age, whereas younger children did not seem to be significantly affected by classroom assignment.

As noted, these findings stand in contrast to enthusiasm that has been expressed for movement toward more mixed-age classrooms in preschool education (e.g., Bredekamp, 1987; Katz et al., 1990). As we have argued, the empirical evidence for this enthusiasm has been decidedly mixed and inconclusive to this point and, more important, has relied on relatively small samples, typically in suburban settings. In this context, the present research strongly suggests that reconsideration of the issue of classroom age composition in early childhood education is warranted.

Most relevant, this research speaks to the consequences of variance in classroom age composition as it naturalistically occurs in urban preschool classrooms today. Although it could well be that mixed-age contexts have the potential to benefit children, in this large and diverse urban sample this was not the case. The opposite proved true. For reasons yet to be fully elaborated, and which merit further research, older children in mixed-age classrooms developed at a slower rate than older children in single-age classrooms.

### Theoretical Implications

The findings from the present investigation strongly support the theory-based predictions offered by Piaget (1932) and others, who argued that interacting with peers who are close in age and ability will result in optimal learning. At the same time, these findings are not entirely inconsistent with predictions offered by Vygotsky (1930/1978) and others, who argued for mixed-age interaction principally on the basis of the merits implicit for younger children in these contexts. These authors posited that younger children could benefit from interacting with older, more competent children. In this regard, their prediction was unsupported. However,

implicit in the Vygotskian model are the potential negative consequences for those who are older and more competent in mixed-age interaction. Thus, in terms of the relative advantage or disadvantage for different children in mixed-age interaction, the data from this study provide some support for the assertions made by Vygotsky and his colleagues. That is, one interpretation of the Vygotskian model is that variance in age composition or ability among interaction partners should be relatively less beneficial for those older children who are higher in ability. Our investigation supported this relativistic aspect of the Vygotskian model, such that although the influence of developmental age variance was negligible for developmentally younger children, there were significant negative consequences for developmentally older children.

The theoretical accounts for the influence of mixed- versus restricted-age groupings offered by Piaget (1932) and Vygotsky (1930/1978) focused primarily on the influence of peer interaction. However, it is likely that those supervising children (teachers, in the present investigation) may behave differently in mixed- versus restricted-age groupings as well. That is, as a result of being placed in mixed-age versus restricted-age classrooms, teachers may change their modes of instruction and interaction. Although exploring the dynamics through which teachers may be influenced and, in turn, exert influence on the children in mixed- versus restricted-age classrooms was beyond the scope of this study, it remains an important issue to consider.

### *Limitations and Conclusions*

Differences in these findings relative to other published studies may, in part, be attributed to the time horizon used in assessing the influence of classroom age composition. The vast majority of studies on classroom age composition have been cross-sectional (i.e., single time point as opposed to change) in design (e.g., Dunn et al., 1996; Field, 1982; Goldman, 1981; Urberg & Kaplan, 1986; for exceptions, see Bailey et al., 1993, and Winsler et al., 2002). A strength of the present investigation was that development was assessed longitudinally. However, the full influence of mixed-age classrooms may take several years to manifest. One future direction for this line of research would be to explore the influence of classroom age composition on developmental change across multiple time points, extending from 6 months (as in the present research) to several years after initial exposure to these classrooms.

A strength of this research was the use of assessments of constructs at multiple time points; however, data were only collected at two time points. A logical extension of the basic approach we have outlined in this research would involve assessments at three or more time points. This would permit exploration into the possibility of both linear and nonlinear trajectories.

Another limitation of this research involves the correlational nature of these data. Empirical investigations that manipulate the age composition of preschool classrooms, with random assignment to condition, are warranted. As an alternative, when large-scale institutional policy changes are made affecting the age composition of preschool classrooms, such cases represent pseudoexperiments that may be used to more strongly establish a causal relation between classroom age composition and developmental outcomes (e.g., Winsler et al., 2002).

Finally, the uniformly high ratings of classroom quality (ECERS-R) in this sample were not conducive to appropriately

testing the potential for classroom quality to moderate the negative effect of age variance observed in mixed-age classrooms. Further investigations are called for, targeting samples that include classrooms with greater variance in quality and the inclusion of additional indicators of classroom quality.

Despite these limitations, this investigation should be considered a significant contribution, as it represents an empirical investigation of preschool classroom age composition on a far larger scale than previously completed. It introduces a novel, and potentially generative, methodological approach for investigating the influence of classroom age composition (i.e., treating age composition as a continuous variable). Furthermore, this question was explored in terms of both chronological and developmental age composition in these classrooms, and the results were remarkably consistent across indicators of classroom composition and domains of development. The results support initiatives to maintain and facilitate movement toward preschool classrooms with more restricted age composition, at least insofar as age composition is a factor considered independently from curriculum considerations. As noted, the influence of age composition may be dynamically related to teachers' modes of instruction, to the extent that teachers are influenced by classroom age composition. The present investigation leaves open the possibility that mixed-age preschool classrooms coupled with curricula tailored to such climates could indeed be as good as or even superior to the typical restricted-age classroom. Specifically, our data suggest that such mixed-age-classroom-tailored curricula should address the needs of more mature, developmentally advanced children, who seem to have fared the worst under these conditions in our sample.

Ultimately, a thorough analysis of this issue must also take into consideration the economics of mixed- versus restricted-age classrooms. In areas of the country in which preschool classrooms are easily filled to capacity, it seems most prudent at this juncture to advocate for more restricted age composition. However, in parts of the country in which preschool classrooms are less easily filled, it may become significantly more cost effective to permit greater diversity in classroom age composition. As such, we cannot unilaterally condemn mixed-age classrooms but would instead implore educators compelled to work in these settings to make special efforts to provide individualized, optimal challenges for children who may otherwise be disadvantaged.

## Appendix A

### Multilevel Equations for Models 1–8

We estimated child-level (Level 1) Time 2 (T2) Child Observation Record (COR) scores by means of the following equation:

$$\begin{aligned} \text{T2 COR} = & \beta_0 + \beta_1(\text{Child's Age}) + \beta_2(\text{T1 COR}) \\ & + \beta_3(\text{Gender}) + e, \end{aligned}$$

where  $\beta_0$  refers to the intercept (i.e., the average COR score at Time 2);  $\beta_1$ ,  $\beta_2$ , and  $\beta_3$  represent the maximum likelihood estimate of the population slopes estimating Time 2 COR score from the child's age, child's T1 COR score, and gender, respectively; and  $e$  is error.

We estimated classroom-level (Level 2) effects as follows:

$$\beta_0 = \gamma_{00} + \gamma_{01}(\text{Age Composition}) + \gamma_{02}(\text{Class Size}) + u_0,$$

$$\beta_1 = \gamma_{10} + \gamma_{11}(\text{Age Composition}) + u_1,$$

$$\beta_2 = \gamma_{20} + u_2, \text{ and}$$

$$\beta_3 = \gamma_{30} + u_3.$$

We estimated the combined model as follows:

$$\begin{aligned} \text{T2 COR} = & \gamma_{00} + \gamma_{01}(\text{Age Composition}) \\ & + \gamma_{02}(\text{Class Size}) + \gamma_{10}(\text{Child's Age}) \end{aligned}$$

$$\begin{aligned} & + \gamma_{11}(\text{Age Composition})(\text{Child's Age}) \\ & + \gamma_{20}(\text{T1 COR}) + \gamma_{30}(\text{Gender}) + u_0 + u_1(\text{Child's Age}) \\ & + u_2(\text{T1 COR}) + u_3(\text{Gender}) + e, \end{aligned}$$

where  $\gamma_{00}$  refers to the child-level intercept for an average classroom;  $\gamma_{01}$  represents the maximum likelihood estimate of the population slope estimating average levels of Time 2 COR scores across all classrooms from classroom-level age composition;  $\gamma_{02}$  represents the maximum likelihood estimate of the population slope estimating average levels of Time 2 COR scores across all classrooms from classroom-level size (i.e., the number of students in the classroom) and  $u_0$  represents error in estimating this intercept;  $\gamma_{10}$  represents the maximum likelihood estimate of the population slopes estimating Time 2 COR score from child's age and  $u_1$  represents error related to that estimate;  $\gamma_{20}$  represents the maximum likelihood estimate of the population slopes estimating Time 2 COR score from Time 1 COR score and  $u_2$  represents error related to that estimate;  $\gamma_{30}$  represents the maximum likelihood estimate of the population slopes estimating Time 2 COR score from gender and  $u_3$  represents error related to that estimate; and  $\gamma_{11}$  represents the maximum likelihood estimate of the cross-level interaction between child-level age and classroom-level age composition.

## Appendix B

## Multilevel Equations for Models 9–16

We estimated child-level (Level 1) Time 2 COR scores by the following equation:

$$\begin{aligned} \text{T2 COR} = & \beta_0 + \beta_1(\text{Child's Developmental Age}) \\ & + \beta_2(\text{Child's Age}) + \beta_3(\text{Gender}) + e, \end{aligned}$$

where  $\beta_0$  refers to the intercept (i.e., the average COR score at Time 2);  $\beta_1$ ,  $\beta_2$ , and  $\beta_3$  represent the maximum likelihood estimate of the population slopes estimating Time 2 COR score from the child's developmental age, child's age, and gender, respectively; and  $e$  is error.

We estimated classroom-level (Level 2) effects as follows:

$$\begin{aligned} \beta_0 = & \gamma_{00} + \gamma_{01}(\text{Developmental Age Composition}) \\ & + \gamma_{02}(\text{Class Size}) + u_0, \\ \beta_1 = & \gamma_{10} + \gamma_{11}(\text{Developmental Age Composition}) + u_1, \\ \beta_2 = & \gamma_{20} + u_2, \text{ and} \\ \beta_3 = & \gamma_{30} + u_3. \end{aligned}$$

We estimated the combined model as follows:

$$\begin{aligned} \text{T2 COR} = & \gamma_{00} + \gamma_{01}(\text{Developmental Age Composition}) \\ & + \gamma_{02}(\text{Class Size}) + \gamma_{10}(\text{Child's Developmental Age}) \\ & + \gamma_{11}(\text{Developmental Age Composition}) \\ & (\text{Developmental Age}) + \gamma_{20}(\text{Child's Age}) \end{aligned}$$

$$\begin{aligned} & + \gamma_{30}(\text{Gender}) + u_0 + u_1(\text{Child's Developmental Age}) \\ & + u_2(\text{Child's Age}) + u_3(\text{Gender}) + e, \end{aligned}$$

where  $\gamma_{00}$  refers to the child-level intercept for an average classroom;  $\gamma_{01}$  represents the maximum likelihood estimate of the population slope estimating average levels of Time 2 COR scores across all classrooms from classroom-level developmental age composition;  $\gamma_{02}$  represents the maximum likelihood estimate of the population slope estimating average levels of Time 2 COR scores across all classrooms from classroom-level size (i.e., the number of students in the classroom) and  $u_0$  represents error in estimating this intercept;  $\gamma_{10}$  represents the maximum likelihood estimate of the population slopes estimating Time 2 COR score from child's developmental age (i.e., Time 1 COR) and  $u_1$  represents error related to that estimate;  $\gamma_{20}$  represents the maximum likelihood estimate of the population slopes estimating Time 2 COR score from child's age and  $u_2$  represents error related to that estimate;  $\gamma_{30}$  represents the maximum likelihood estimate of the population slopes estimating Time 2 COR score from gender and  $u_3$  represents error related to that estimate; and  $\gamma_{11}$  represents the maximum likelihood estimate of the cross-level interaction between child-level developmental age and classroom-level developmental age composition.

# Peer Victimization and Academic Achievement in a Multiethnic Sample: The Role of Perceived Academic Self-Efficacy

Jochem Thijs and Maykel Verkuyten  
Utrecht University

This study examines the link between perceived peer victimization and academic adjustment in an ethnically diverse sample of 1,895 Grade 6 students nested within 108 school classes. It was hypothesized that students' academic self-efficacy mediates the (negative) link between victimization experiences and academic achievement outcomes. Multilevel analyses were used to test this hypothesis and to explore whether there are differences between ethnic minority and majority group children. Results indicated that peer victimization was negatively associated with both relative class-based, and absolute test-based measures of academic achievement. These associations were similar across different school classes. As expected, the link between victimization and achievement was mediated by perceived academic self-efficacy, suggesting that victimized students did less well academically because they considered themselves to be less competent. The lower perceived self-efficacy of victimized children could be partly attributed to lower global self-esteem and depressed affect. Results were largely similar for ethnic minority and majority group children.

**Keywords:** peer victimization, academic achievement, perceived academic self-efficacy, ethnic minority students

Peer victimization is a considerable problem for a substantial number of children (Juvonen, Nishina, & Graham, 2000). The term *peer victimization* refers to the individual experience of aggressive or negative behaviors by others, including name calling or active exclusion (Hawker & Boulton, 2000; Lopez & DuBois, 2005). There is a bulk of evidence suggesting that victimization experiences can have negative consequences for children's psychosocial functioning. Hawker and Boulton (2000) summarized this evidence in a meta-analysis of cross-sectional studies covering almost 20 years of research. Peer victimization had significant negative effects on all adjustment variables examined in the analysis, including depression, loneliness, global self-esteem, social self-concept, general anxiety, and social anxiety. Although these effects were moderate in size ( $r = .19-.45$ ), the range of affected outcomes attests to the seriousness of the phenomenon (Hawker & Boulton, 2000).

More recently, researchers have focused on the links between peer victimization and academic adjustment, and, in particular, children's achievement outcomes. Studies relying on cross-sectional data have shown that victimized children receive lower grades than their more accepted classmates (Buhs & Ladd, 2001; Graham, Bellmore, & Mize, 2006; Lopez & DuBois, 2005; Schwartz, Farver, Chang, & Lee-Shin, 2002). Further, longitudinal research suggests that these lower achievement outcomes are consequences rather than causes of victimization. It has been shown, for instance, that changes in self-perceived victimization (together

with self-worth and loneliness) are uniquely predictive of GPA (Juvonen et al., 2000), that victimization predicts decreased levels of academic achievement (Buhs, Ladd, & Herald, 2006), and also that academic functioning does not predict changes in peer victimization (Schwartz, Gorman, Nakamoto, & Toblin, 2005). Notwithstanding these research findings, the mechanisms by which victimization affects academic achievement are not fully clear.

Empirical attempts to explain the academic consequences of peer victimization have focused on the role of psychological adjustment. Several studies have shown that maladjustment mediates the negative effects of peer victimization on children's scholastic functioning, including their academic outcomes (Austin & Joseph, 1996; Graham et al., 2006; Juvonen et al., 2000; Lopez & DuBois, 2005; Schwartz et al., 2005). Most of these studies have relied on global or composite measures of emotional well-being, such as depression, loneliness, or anxiety. The findings are consistent with motivational models stating that motivated academic behavior requires a state of emotional well-being (Boekaerts, 1993) or secure relatedness (Connell & Wellborn, 1991; Ryan & Deci, 2000a, 2000b). Clearly, children who are victimized in school do not experience this state, which puts them at risk for unfavorable academic outcomes.

Theoretically, emotional well-being is not the only prerequisite for academic achievement. Both motivational and self-concept theorists posit that self-perceived efficacy is essential as well. Perceptions of efficacy refer to the confidence in one's ability to organize and execute a given course of action or accomplish a task. Proponents of process models of motivation argue that self-directed behaviors and, hence, positive achievement outcomes are dependent on feelings of personal efficacy, in addition to relatedness and autonomy (Connell & Wellborn, 1991; Ryan & Deci, 2000a, 2000b; Skinner, Wellborn, & Connel, 1990). Furthermore,

it has been concluded that students' academic self-concepts, which include their perceptions of academic efficacy, have reciprocal relations with academic achievement outcomes. Not only are these self-perceptions grounded in actual accomplishments, they also have motivating properties leading to better achievement outcomes (Guay, Larose, & Boivin, 2004; Marsh, Trautwein, Lüdtke, Koller, & Baumert, 2005; Trautwein, Lüdtke, Koller, & Baumert, 2006; Valentine, DuBois, & Cooper, 2004).

There are indications that peer victimization can have a negative impact on children's academic self-efficacy. For instance, negative correlations have been reported between peer victimization experiences and perceived academic competence (Austin & Joseph, 1996; Verkuyten & Thijs, 2002). In addition, Flook, Repetti, and Ullman (2005) found that children's perceived academic self-efficacy was negatively affected by experiences with peer rejection, which is considerably related to peer victimization and has similar correlates (Lopez & DuBois, 2005).<sup>1</sup> A possible reason for these findings is that victimized (or rejected) children receive negative messages about themselves, which negatively affect their overall self-evaluations (Graham & Juvonen, 1998; Hawker & Boulton, 2000), and which may extend to their self-efficacy in the academic domain (Flook et al., 2005).

Given its (anticipated) relations with peer victimization and academic achievement, it is reasonable to expect that academic self-efficacy mediates the link between victimization and achievement. Two of the aforementioned studies provide indirect support for this hypothesis. First, Lopez and DuBois (2005) obtained empirical support for a model in which negative (social and global) self-evaluations mediated the links between peer victimization and peer rejection, on the one hand, and academic as well as behavioral and emotional problems, on the other hand. Although the self-evaluations in that study pertained to the social and global domains rather than to the academic domain, the results indicate that victimization diminishes feelings of efficacy. Second, Flook et al. (2005) examined how peer rejection was related to children's academic performance. It appeared that both perceived academic self-efficacy and internalizing symptoms were independent mediators of this relationship. This indicates that peer rejection and possibly also peer victimization put children at risk for low academic outcomes, not only because it diminishes their sense of emotional well-being but also because it diminishes their sense of academic competence (Flook et al., 2005).

The present research focused on perceived academic self-efficacy as a mediator of the (hypothesized) link between peer victimization and academic achievement. In doing so, we went beyond Flook et al.'s study (2005) in four ways. First, we operationalized students' academic achievement outcomes in two manners. Like Flook et al. (2005), we relied on class-based measures by assessing students' academic accomplishments relative to their classmates. In addition, we included a measure of academic achievement based on standardized tests scores. The use of this score allowed us to examine the impact of victimization beyond the classroom. The distinction between relative and more absolute measures might also be relevant for the mediating role of perceived academic self-efficacy. It has been argued, and found, that academic self-concept has a stronger influence on class-based relative performance than on standardized achievement outcomes (Marsh, 1987; Marsh et al., 2005).

Second, we examined the role of two covariates. Following Flook et al. (2005) who examined the role of internalizing problems, we included a measure of depressed affect to control for diminished levels of well-being associated with victimization. However, we also included a measure of global self-esteem. This allowed us to examine the specific suggestion that the hypothesized link between victimization and perceived academic self-efficacy can be explained as a generalized effect of negative global self-feelings (see Flook et al., 2005; Lopez & DuBois, 2005).

Third, we used a two-level design by examining children nested within a large number of school classes. As a result, we could investigate whether the statistical effects of victimization are similar or different across different classes. Such an examination is of theoretical interest as it can improve our understanding of the potential impact of negative peer treatment. Moreover, it has practical relevance, because it can indicate whether the classroom context should be considered in attempts to prevent or diminish the negative effects of peer victimization on academic outcomes.

The fourth feature of our study was the ethnic diversity of the sample. Like most western countries, the Netherlands hosts a variety of different ethnic groups. It is important that this variety is represented in research. Moreover, use of a multiethnic sample allows examination of whether the links among peer victimization, perceived academic self-efficacy, and achievement outcomes are similar for ethnic majority and ethnic minority group students. Relatively few studies have examined peer victimization and its various effects on children from ethnic minority groups (e.g., Hanish & Guerra, 2000; Storch, Zelman, Sweeney, Danner, & Dove, 2002; Verkuyten & Thijs, 2006). Peer victimization may have different meanings for minority versus majority students. There is evidence, for example, that minority children more often understand victimization experiences as instances of ethnic discrimination (Verkuyten & Thijs, 2000, 2006). It is important to examine these experiences as several studies have found negative effects of ethnic discrimination on children's academic achievement (Graham et al., 2006; Neblett, Philip, Cogburn, & Sellers, 2006; Wong, Eccles, & Sameroff, 2003).

The present study had two goals. First, we examined the relations among peer victimization, perceived academic self-efficacy, and (relative and absolute) academic achievement in an ethnically diverse sample of early adolescents. Our main hypothesis was that perceived academic self-efficacy mediates the (negative) link between children's victimization experiences and their academic achievement outcomes. This hypothesis was tested without and with depressed affect and global self-esteem as covariates. The inclusion of the latter allowed us to evaluate the more specific subhypothesis that peer victimization negatively affects children's academic self-efficacy through negative global self-feelings. The two hypotheses are schematically depicted in Figure 1. The second goal of the study was to explore whether these expected associations hold for both ethnic majority and minority groups.

<sup>1</sup> Whereas peer victimization reflects negative behaviors by individual peers, peer rejection reflects negative attitudes by the peer group (Lopez & DuBois, 2005).

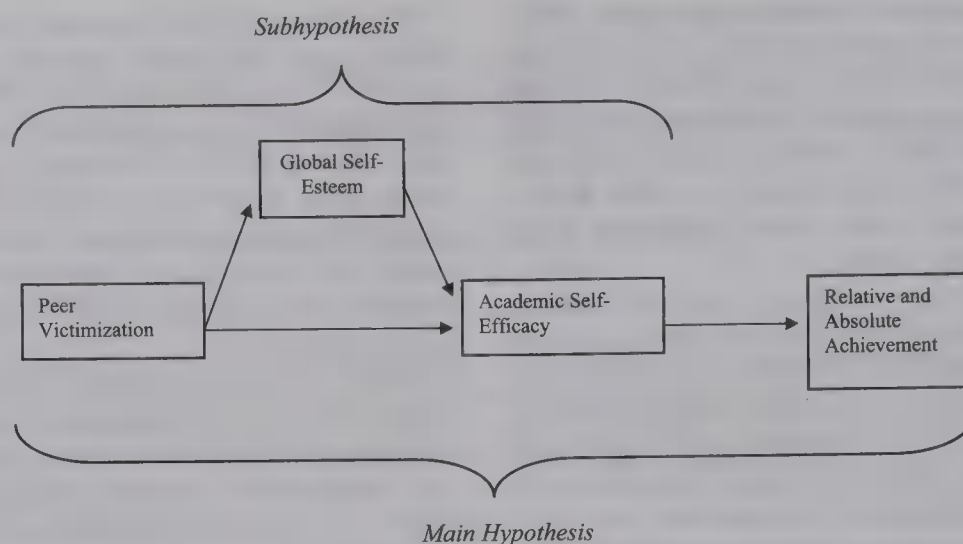

Figure 1. Scheme of hypothesized relations.

## Method

### Participants

Participants were 1,895 Grade 6 students from 108 classes in 81 regular primary schools in the Netherlands. Of these children, 50.6% were girls. According to their ethnic self-definition and the reported ethnicity of their parents, 844 of these children were identified as Dutch. According to the same criteria, 605 children belonged to the three largest minority groups in the Netherlands. They were identified as Turkish ( $n = 299$ ), Moroccan ( $n = 237$ ), or Surinamese ( $n = 69$ ). The remaining 446 children were of mixed or different ethnicities.

### Procedures

All students were tested in the second half of Grade 6 (the spring, i.e., when they already had participated in a standardized achievement test; see next section). Each of them completed a questionnaire under supervision and simultaneously within their classrooms. In the introduction to this questionnaire, students were asked to answer questions about school and themselves, and their anonymity was guaranteed. Almost all students were able to complete the questions within 40 min. The measures of interest to the present study were included in the following fixed order: peer victimization, global self-esteem, academic self-efficacy, depressed affect, relative achievement, and absolute achievement.

There were no missing variables for 95% of the cases. For the remaining children, 2%–9% of the values were missing ( $Mdn = 2\%$ ). We imputed these scores using the expectation maximization algorithm. This procedure is adequate when values are missing at random (Bernaards & Sijtsma, 1999).

### Measures

**Peer victimization.** Perceptions of peer victimization were assessed with four items, which referred to the frequencies of being teased or called names and the frequencies of being excluded in the school and neighborhood. These items were developed by the authors from Dutch research on early adolescents' own understanding of peer victimization (Verkuyten, Kinket, & van der

Wielen, 1997). In previous studies, these items were found to be negatively related to children's global self-esteem (Verkuyten & Thijs, 2001) and depressed affect (Verkuyten, 2003), supporting their concurrent validity. The items were scored on a scale ranging from 1 (*no, never*) to 5 (*yes, very often*). Principal components analysis (PCA) on the items revealed one component that explained 54% of the variance. Cronbach's alpha (for internal consistency) was .72.

**Academic self-efficacy.** Perceived academic self-efficacy was assessed with four items adapted from the scholastic competence scale of Harter's (1988) Self-Perception Profile for Adolescents (SPPA). The SPPA is an established self-concept measure containing eight subscales for domain-specific self-evaluations for which adequate internal consistencies (Cronbach's alpha's  $> .73$ ) and strong factorial validity have been reported (Harter, 1988). Harter (1988) did not report external validity findings for the SPPA (see also Byrne, 1996). However, studies using adaptations of this measure have reported moderate relations between the scholastic competence scale and students' academic grades ( $r > .34$ ; Soenens & Vansteenkiste, 2005; Wichstrøm, 1995).

In the SPPA, respondents are required to choose one statement from a pair of two opposite statements and then to express their level of agreement with their choice. However in the present research, as in other studies (Soenens & Vansteenkiste, 2005; Wichstrøm, 1995), children were presented with single statements rather than paired statements. We chose this format because in previous studies, we found that many children had difficulties with the paired format. Agreement with the items was rated on a scale ranging from 1 (*no, certainly not*) to 4 (*yes, certainly*). For example, children were asked whether they often forget what they learn and whether they are able to learn very well. Cronbach's alpha was .62 for this scale. The items loaded on one component that explained 47% of the variance.

**Relative achievement.** Elementary school children in the Netherlands receive their grades from their teachers. As in other countries, these grades are based (in part) on students' achievements relative to those of their classmates. We collected information on perceived relative academic position within the classroom by means of three Willig Scales (see Burns, 1979). The Willig Scale

is a self-anchoring, 11-step rating scale that has been used in previous studies among ethnic majority and minority early adolescents in the Netherlands (Verkuyten, Thijs, & Canatan, 2001). The top of the scale (10) marks the best performing student in one's class (i.e., the student receiving the highest grades in class), and the lowest step (0) marks the worst performing student. Children were asked to use this scale to rate their general performance, their achievement in language learning, and their achievement in mathematics. These three ratings loaded on one component accounting for 69% of the variance, and they yielded a Cronbach's alpha of .75. Students' mean score on this relative achievement measure was 6.72 ( $SD = 1.60$ ). Its distribution was slightly skewed to the left ( $-.424, p < .001$ ) but it had no significant kurtosis. Supporting its concurrent validity, previous studies found that this measure was positively related to academic motivation, academic competence, and school satisfaction (Verkuyten & Thijs, 2002; Verkuyten et al., 2001).

**Absolute achievement.** To obtain a more absolute measure of their academic achievement, we used students' self-reports of their official secondary school advice. In the Netherlands, students receive their secondary education advice from their teachers in the final grade (Grade 6) of primary school. Teachers take several considerations into account when giving this advice. However, the advice is predominantly based on students' scores on a standard national school achievement test (CITO test) and is highly correlated with these scores ( $r > .85$ ; Driessen & Doesborgh, 2005; Kapinga, 2002). Thus, the educational advice is a valid measure of students' academic achievement.

The secondary Dutch education system has five levels: a) initial professional education, b) general and vocational education, c) senior general secondary education, d) university preparatory education atheneum, and e) university preparatory education gymnasium (high-level grammar school). Teachers' advice to children involves one type of education or the combination of two bordering levels of education. Our absolute achievement measure was a 7-point scale including each level and the combinations of b and c, and c and d.<sup>2</sup> The distribution of this scale had no significant kurtosis. However, it was slightly skewed to the right (.918,  $p < .001$ ). The mean score on this measure was 2.73 ( $SD = 1.74$ ), and the median was 2.<sup>3</sup>

**Depressed affect.** Three items that inquired about sadness, nervousness, and fear were used to measure students' depressed affect. Cronbach's alpha was .62. The items were taken from the Profile of Mood States (McNair, Lorr, & Droppleman, 1971) on the bases of their face validity. We used the same 4-point response format (from 1, *no, certainly not* to 4, *yes, certainly*) used for the Academic Self-Efficacy Scale. PCA on these three items yielded one component that explained 58% of the variance.

**Global self-esteem.** Global self-esteem was assessed with items from the well-known 10-item Rosenberg (1965) Self-Esteem Scale. Early adolescents have been found to have difficulties in responding to negatively worded self-esteem items (Marsh, 1986). Therefore, we used the five positively worded items of the Rosenberg scale. In addition, each item had the same four-point response format as the perceived academic self-efficacy measure. Cronbach's alpha for these five items was .75. The items loaded on one component that explained 52% of the variance. In support of the concurrent validity of the scale, previous Dutch research has shown that this abbreviated measure is negatively related to de-

pressed affect (Verkuyten, 2003) and positively to self-concept stability (Verkuyten, 1995) and ethnic self-regard (Verkuyten & Thijs, 2004).

### Data Analysis

Participants were sampled through their classes rather than individually. As children attending the same class tend to be alike in some respects, data for individual participants were probably not independent. When dependent data are analyzed with conventional statistical tests, standard errors are underestimated, and results may be spuriously significant (Snijders & Bosker, 1999). This can be prevented with multilevel analyses. Multilevel analysis can correct for dependencies between observations for individual subjects (e.g., pupils) nested within the same units (e.g., classes). Moreover, it can be used to analyze variable numbers of subjects per unit (Snijders & Bosker, 1999). In this study, we conducted multilevel analyses with MLwiN Version 2.0 (Rasbash, Browne, Healy, Cameron, & Charlton, 2004) using the iterative generalized least squares algorithm. Two levels were specified: Level 1 pertaining to individual differences within classes and Level 2 pertaining to differences between classes.<sup>4</sup>

The measures of relative and absolute achievement were strongly related (see Table 1). To examine whether both measures were similarly affected by the independent variables, we analyzed them simultaneously in multivariate multilevel models. For this purpose, both measures were standardized, and an additional level was specified. This level, Level 0, was included to define the multivariate structure (Goldstein, 1995; Snijders & Bosker, 1999). All other variables were examined with univariate multilevel models.

The multivariate multilevel model is an extension of the univariate model. A univariate two-level regression model with one fixed Level 1 predictor  $x$  can be expressed by  $y_{ij} = \beta_0 + \beta_1 x_{ij} + e_{ij} + u_j$ , with  $\text{var}(e_{ij}) = \sigma_e^2$  and  $\text{var}(u_j) = \sigma_u^2$ . In this equation, the subscripts  $i$  and  $j$  denote units at Level 1 (e.g., students) and Level 2 (e.g., classes), respectively;  $\beta_0$  is the intercept and  $\beta_1$  is the slope; and  $e_{ij}$  and  $u_j$  are the residuals for each level. The two-variate variant of the univariate model is represented by  $y_{hij} = \beta_{01}z_{1hij} + \beta_{02}z_{2hij} + \beta_{11}z_{1hij}x_i + \beta_{12}z_{2hij}x_i + e_{1ij}z_{1hij} + e_{2ij}z_{2hij} + u_{1j}z_{1hij} + u_{2j}z_{2hij}$ , with  $\text{var}(e_{1ij}) = \sigma_{e1}^2$ ,  $\text{var}(e_{2ij}) = \sigma_{e2}^2$ ,  $\text{cov}(e_{1ij}, e_{2ij}) = \sigma_{e1e2}$ ,  $\text{var}(u_{1j}) = \sigma_{u1}^2$ ,  $\text{var}(u_{2j}) = \sigma_{u2}^2$ , and  $\text{cov}(u_{1j}, u_{2j}) = \sigma_{u1u2}$ . Here, the additional level (Level 0) is indicated by the subscript  $h$ . In

<sup>2</sup> Within this scaling, the lowest two levels and the highest two levels are relatively close to each other, and many children are given advice that combines Levels 2 and 3, or Levels 3 and 4. For these reasons, it was decided to include these combinations as separate scale-points.

<sup>3</sup> Because both achievement measures were skewed, we looked for outliers. There were no extreme scores on the absolute measure. However, for five cases, relative achievement scores were more than 3.29 standard deviations (maximum  $SD$ , 4.21) below the sample mean corresponding to  $p < .001$  (Tabachnick & Fidell, 1996). These cases were retained in the analyses because analyses without them yielded virtually the same results, and sample size was large.

<sup>4</sup> The data had a three-level structure with students nested in classes nested in schools. However, three-level models could not be examined because class and school levels were heavily confounded as 60 schools (74%) were represented by only one class each. Most Dutch primary schools have only one class for each grade.

Table 1  
*Intercorrelations, Means, and Variance Components of All Variables*

Variable	1	2	3	4	5	6	M	Variance		
								Level 1	Level 2	Total
1. Peer victimization	—						1.98	.466	.019**	.485
2. Academic self-efficacy	-.25**	—					2.98	.263	.007*	.270
3. Relative achievement	-.16**	.53**	—				0.00	.977	.023*	1.00
4. Absolute achievement	-.10**	.43**	.58**	—			0.00	.912	.090**	1.00
5. Depressed affect	.36**	-.35**	-.17**	-.09**	—		2.05	.315	.013**	.328
6. Global self-esteem	-.22**	.32**	.25**	.07**	-.18**	—	3.07	.292	.022**	.314

Note. Both relative and absolute achievement measures were standardized.

\*  $p < .01$ . \*\*  $p < .001$ .

addition,  $z_{1ij} = 1$  and 0 for the first and the second dependent variables, respectively, and  $z_{2ij} = 1 - z_{1ij}$  (see Goldstein, 1995).

For both achievement measures, regression analyses proceeded in two steps. First, the statistical effect of each independent variable was constrained to be similar for both relative and absolute achievement (e.g.,  $\beta_{11}z_{1hij}x_i = \beta_{12}z_{2hij}x_i$ ). Second, if it significantly improved the fit of the model ( $p < .05$ ), this constraint was released, and different effects were estimated for both achievement variables. Unless otherwise indicated, the effects on relative and absolute achievement were different in all analyses.

## Results

### Preliminary Analyses

Before examining the (unique) statistical effects of peer victimization and the mediating role of perceived academic self-efficacy, we estimated the intercorrelations and the variance distributions of all variables. Correlations are shown in the left part of Table 1. As expected, peer victimization was positively related to depressed affect and negatively related to all other variables. These correlations ranged from small to moderate (Cohen, 1988). The relations between the remaining variables were moderate to large, except for the correlations of depressed affect with both achievement variables and global self-esteem and the correlation of global self-esteem with absolute achievement. The right part of Table 1 contains the means and variance components of all variables. The latter were obtained by means of the so-called intercept-only regression model. This model provides an estimate of the intraclass correlation coefficient ( $\rho$ ), which represents the proportion of variance at Level 2 (the class level) for each dependent variable (Snijders & Bosker, 1999). All variables had significant variance at Level 2, indicating systematic differences between classes on these measures. For peer victimization, academic self-efficacy, depressed affect, and relative achievement, these differences constituted a relatively small portion of their total variance: 3.9%, 2.6%, 4.0%, and 2.3%, respectively. For global self-esteem and absolute achievement, the proportion of Level 2 variance was considerably higher. It appeared that 7.0% and 9.0%, respectively, of the individual differences on these variables could be attributed to differences between classes.

### Statistical Effects of Victimization on Academic Functioning

The correlations in Table 1 indicate significant links between peer victimization, on the one hand, and perceived academic self-efficacy and relative and absolute achievement, on the other. However, the two-level structure of our data is not reflected in these correlations. To properly examine whether students' victimization experiences affect within- and between-class differences in the academic variables, we performed multilevel regression models for self-efficacy and both achievement variables. In these models, victimization was included as a single predictor. Its effects were estimated in two steps. First, the effect of victimization was fixed across all classes (Level 2). Second, the regression slopes for victimization were allowed to vary randomly across Level 2. The second step did not result in significant model improvement ( $p > .10$ ) indicating similar effects across all classes. Hence, only the fixed effects of victimization were inspected. These effects are shown in Table 2 (Models 1 and 2).<sup>5</sup>

Consistent with the correlations in Table 1, the analyses revealed that victimization had negative effects on all three academic variables, explaining 6.3% of the variance in perceived academic self-efficacy and 2.7% and 0.8% of the variance in relative and absolute achievement, respectively. Table 2 also shows deviance statistics, which can be used to compare the fit of nested models. Differences between these statistics follow a chi-square distribution, and degrees of freedom are given by the differences in numbers of parameters (Snijders & Bosker, 1999). As shown in Table 2, Models 1 and 2 were significant improvements on the intercept-only models for academic self-efficacy and for relative and absolute achievement.

Given the negative effects of peer victimization and the significant correlations between perceived academic self-efficacy and both relative and absolute achievement (Table 1), it was appropri-

<sup>5</sup> Gender was not included in any of the reported multilevel analyses. Additional analyses, not reported here, indicated significant gender differences for academic self-efficacy, relative achievement, global self-esteem, and depressed affect, with higher means for boys on the first three measures ( $p < .01$ ) and lower scores on depressed affect. However, gender did not interact with victimization, self-efficacy, self-esteem, or depressed affect in the prediction of achievement, nor did its inclusion substantially alter the statistical effects of these predictors.

ate to examine whether self-efficacy mediated the statistical effects of victimization on the achievement measures (see Baron & Kenny, 1986).

The critical test for mediation is that the influence of the predictor on the dependent variable is substantially reduced when the mediator is added as an additional predictor. To conduct this test and to evaluate our main hypothesis (see Figure 1), we regressed both achievement measures on victimization and academic self-efficacy. The result is displayed in the right part of Table 2 (Model 3). Perceived academic self-efficacy had a positive effect on both relative and absolute achievement. This effect was stronger for the first than for the latter measure ( $p < .01$ ) but accounted for more than 17.8% of unique variance in both cases. When the influence of perceived self-efficacy was partialled out, the effects of victimization were considerably reduced. Further

analyses revealed that victimization could only explain an additional 0.2% of the variance in relative achievement compared with 2.7% when perceived self-efficacy was not included (Table 2). In addition, the effect on absolute achievement was no longer significant, implying complete mediation.

#### *Analyses with Covariates*

To investigate whether the aforementioned results were upheld independent of depressed affect and global self-esteem, we added these covariates as predictors to the regression equations in Table 2. First, academic self-efficacy and the achievement variables were regressed on both peer victimization and the covariates. Results are shown under Models 4 and 5 in Table 3. Depressed affect had negative unique effects on self-efficacy and relative achievement,

Table 3

and global self-esteem had positive unique effects on all variables. More important, the effects of victimization were still significant, but they appeared to be smaller compared with those of Models 1 and 2 (Table 2). This seemed to support our subhypothesis that the negative link between peer victimization and self-efficacy could be partly attributed to negative overall self-feelings (see Figure 1).

The Sobel test for mediation was used to examine the indirect effects of peer victimization. An indirect effect of a variable  $x$  on a variable  $y$  through a variable  $z$  can be expressed as  $ab$ , with  $a$  being the effect of  $x$  on  $z$  and  $b$  being the effect of  $z$  on  $y$ . The Sobel test provides a  $z$  statistic for this indirect effect by dividing it by its estimated standard error  $(b^2 s_a^2 + a^2 s_b^2)^{1/2}$ ; see Baron & Kenny, 1986; MacKinnon, Warsi, & Dwyer, 1995). The Sobel test revealed significant indirect effects through global self-esteem and also depressed affect (respectively,  $z = 7.34$ , and  $z = -9.89$ ,  $p < .001$ ). Hence, these variables accounted for part of the relationship between peer victimization and academic self-efficacy.

Next, relative and absolute achievement were regressed on peer victimization, depressed affect and global self-esteem, and academic self-efficacy. Results are displayed under Model 6 (Table 3). Depressed affect had no effect on relative achievement but had a positive (rather than a negative) effect on absolute achievement. Global self-esteem was positively related to relative achievement but had a negative effect on absolute achievement. More important, however, perceived self-efficacy was still a strong significant predictor of both achievement measures (with similar effects on relative and absolute achievement). Thus, it appeared that our previous mediation findings (in Model 3, Table 2) could not be reduced to effects of depressed affect or global self-esteem.

### Ethnic Differences

We examined whether these results applied to ethnic minority (Turkish-Dutch, Moroccan-Dutch, and Surinamese-Dutch) and majority (Dutch) students. In doing so, three dummy variables were created: TUR, MOR, and SUR. These variables were coded, respectively, as 1 for the Turkish-Dutch and 0 for the other children, 1 for the Moroccan-Dutch and 0 for the other children, and 1 for the Surinamese-Dutch and 0 for the other children. When included together, these dummies represented the difference between each of the three minority groups and the group of Dutch children.

Prior to examining the statistical effects of victimization for the different ethnic groups, we examined whether minority and majority students reported similar levels of peer victimization and academic self-efficacy. To this aim, we regressed these variables on the three dummy variables. For peer victimization, 1.5 % of the variance could be attributed to students' ethnic group. Compared with the Dutch students, Turkish and Moroccan students reported fewer instances of peer victimization (respectively,  $b = -.104$ ,  $p < .05$ , and  $b = -.267$ ,  $p < .001$ ). The difference between Surinamese and Dutch students was not significant. For perceived academic self-efficacy, there were no significant differences between the Dutch and the other students.

Next, we examined whether the links between victimization, and perceived academic self-efficacy and both achievement measures differed for minority versus majority students. These variables were regressed on the three dummy variables, on peer victimization, and on the three interactions between the former and

the latter. Inspection of the resulting models revealed that none of the interactions was significant, which indicates that victimization works similarly for the Turkish, Moroccan, and Surinamese as compared with the Dutch students:  $b = -.178$ ,  $p < .001$ , for academic self-efficacy, and  $b = -.186$  (similar) for both achievement variables,  $p < .001$ .

Subsequently, we examined whether for both the minority and the majority students, perceived self-efficacy mediated the relationship between victimization and relative and absolute achievement. Both achievement measures were regressed on the three dummy variables, victimization, academic self-efficacy, and the interactions between the dummy variables and academic self-efficacy. The result is shown under Model 7 in Table 4. Perceived academic self-efficacy and its interactions with the dummy variables were significant predictors of academic achievement. Their effects differed for the relative versus the absolute measure ( $p < .01$ ). Self-efficacy had stronger effects on the relative achievement of the Dutch versus the Turkish and Moroccan students, and the absolute achievement of the Dutch versus all minority children. However, further inspection of the data revealed that the effects of self-efficacy were positive for all ethnic groups: for relative achievement,  $b_{\text{Turks}} = .776$ ,  $b_{\text{Moroccans}} = .695$ ,  $b_{\text{Surinamese}} = .834$ , and  $b_{\text{Dutch}} = 1.200$ ,  $p < .001$ , and for absolute achievement,  $b_{\text{Turks}} = .509$ ,  $b_{\text{Moroccans}} = .709$ ,  $b_{\text{Surinamese}} = .479$ , and  $b_{\text{Dutch}} = .995$ ,  $p < .05$ .<sup>6</sup> When these effects of perceived self-efficacy were partialled out, the effect of victimization was no longer significant. Thus, although academic self-efficacy had different effects of minority versus majority children, it mediated the effects of victimization for all of them.

Finally, we examined whether the effects of victimization as well as the mediation findings were upheld independent of depressed affect and global self-esteem. First, we regressed academic self-efficacy and the achievement variables on the covariates, the dummy variables, and peer victimization. As in the total sample, the effects of peer victimization were significant but also weaker:  $b = -.070$ ,  $p < .001$ , for perceived academic self-efficacy, and  $b = -.186$ ,  $p < .01$ , for both achievement variables. Next, we added depressed affect and global self-esteem to the mediation model (Table 4). As shown under Model 8, the results for self-efficacy and its interactions with the dummy variables were unaffected by the inclusion of these covariates.

### Discussion

This study examined the associations between peer victimization and academic achievement in a large sample of early adolescents. The research had a cross-sectional design, and, hence, our findings do not allow causal conclusions. However, our analysis and interpretation of the direction of effects is consistent with theoretical expectations and with longitudinal findings of victimization being a cause rather than a consequence of low achievement outcomes (Buhs et al., 2006; Juvonen et al., 2000; Schwartz et al., 2005).

<sup>6</sup> The effects for the Dutch children can be directly inferred from Models 7 and 8. The statistical effects for the minority children can be obtained by adding the regression coefficient for each minority group to the coefficient for the Dutch children.

Note. TUR is a dummy variable, with Turkish = 1 and Other = 0; MOR is a dummy variable, with Moroccan = 1 and Other = 0; SUR is a dummy variable, with Surinamese = 1 and Other = 0; For both peer victimization and depressed affect, common coefficients were estimated.

\*  $p < .01$ . \*\*  $p < .001$ . <sup>†</sup>  $p < .05$ .

As expected, students who reported more victimization experiences had less favorable achievement outcomes. This finding is in agreement with the results of other studies showing negative links between peer victimization and academic adjustment. These other studies have either relied on relative measures of achievement such as GPAs or teacher ratings (Graham et al., 2006; Juvonen et al., 2000; Lopez & DuBois, 2005; Schwartz et al., 2002) or on standardized achievement measures (Buhs & Ladd, 2001; Buhs et al., 2006). In the present study, students' relative and absolute academic achievements were simultaneously analyzed. Hence, we could examine the impact of victimization both within and beyond the classroom. Our results indicate that victimization had a stronger statistical effect on the class-based relative achievement measure as compared with the absolute measure. Thus, the impact of victimization was most pronounced for children's accomplishments relative to their classmates. Still, this influence was not confined to students' relative achievement but extended to their official secondary education advice, which can be considered a strong indicator of their absolute achievement (Driessen & Doesborgh, 2005; Kapinga, 2002). Although the links between victimization and achievement are not very strong, they are important because of the potential influence of victimization experiences on students' future academic and occupational careers.

The multilevel structure of the data allowed us to examine peer victimization and its impact within and between classes. As in previous research (Verkuyten & Thijs, 2000), there were systematic between-class differences in the level of peer victimization. However, the effects of victimization were similar across the different classes. This suggests that victimization experiences have similar meanings for children inhabiting different classrooms and

also that shared classroom factors do not affect these meanings. Of course, this is not to say that victimization cannot have different consequences for individual students. Rather, the findings indicate that any practical attempt to prevent lower achievement as a consequence of peer victimization should focus on the characteristics and needs of individual students.

In support of our main hypothesis, the negative associations between perceived victimization and achievement were mediated by perceptions of lower academic self-efficacy. In agreement with previous findings (Flook et al., 2005; Verkuyten & Thijs, 2002), this suggests that children who experience higher rates of peer victimization consider themselves to be less academically competent. This link was independent of global self-esteem and depressed affect. Consistent with our subhypothesis, self-esteem explained a significant part of the link between victimization and self-efficacy. However, this link still existed when its influence was partialled out, and thus, the low perceived academic self-efficacy among victimized students could only be partly attributed to general negative self-evaluations (cf., Flook et al., 2005; Lopez & DuBois, 2005). This raises the question of the specific process behind the association between peer victimization and academic self-efficacy. Perhaps it is not so much global self-esteem but, rather, general self-efficacy that mediates this link. General self-efficacy and global self-esteem are strongly related constructs but the latter emphasizes affective aspects of the self and the former refers to confidence in one's ability to accomplish tasks (Chen, Gully, & Eden, 2004). Another explanation is that the negative messages about themselves that children receive in peer victimizations may involve their intellectual and academic abilities (e.g.,

“stupid,” “dumb”). Future studies are needed to explore these interpretations.

Students' perceived self-efficacy was related to their academic outcomes. This finding supports the notion that perceived self-efficacy has motivating properties leading to better achievement outcomes (Connell & Wellborn, 1991; Marsh et al., 2005; Ryan & Deci, 2000a, 2000b; Skinner et al., 1990; Trautwein et al., 2006). Moreover, our results are consistent with Marsh et al.'s (2005) conclusion that perceived academic self-concept has a stronger influence on school-based performance measures than on standardized achievement outcomes.

Our finding that depressed affect did not affect the mediating role of perceived self-efficacy is consistent with the work of Flook et al. (2005) who showed that self-efficacy was a unique predictor of school outcomes independent of children's internalizing symptoms. However, contradictory to the results of these researchers, depressed affect had no unique negative statistical effects on academic achievement in the present study. Perhaps, this was due to measurement differences. Flook et al. (2005) used a broad, 26-item measure for internalizing symptoms, which did not only entail depressed affect and anxiety but also withdrawal and somatic complaints. Moreover, they relied on teacher reports, rather than self-reports, to assess these symptoms. The absence of a unique, negative link between depressed affect and achievement might seem inconsistent with models of motivation that hold that self-directed behaviors are dependent on emotional well-being (Boekaerts, 1993) or on feelings of self-efficacy, autonomy, and relatedness (Connell & Wellborn, 1991; Ryan & Deci, 2000a, 2000b; Skinner et al., 1990).<sup>7</sup> Yet, it should be noted that our study was not intended to test these models and that our measure of depressed affect was probably too narrow to represent the concepts of well-being or relatedness. On the basis of the present findings, it seems reasonable to conclude that academic self-efficacy predicts students' achievement independent of their socioemotional welfare. Still, future studies are needed to further support this conclusion.

An important feature of our study was the ethnic diversity of the sample. This allowed us to examine the impact of victimization on the academic adjustment of ethnic minority (Turkish-Dutch, Moroccan-Dutch, and Surinamese-Dutch) as compared with majority (Dutch) students. Our results show that the role of victimization and the mediation by academic self-efficacy were independent of minority status. Therefore, our findings support a “one model fits all” approach to studying the academic adjustment of early adolescents in multiethnic settings. However, although there were no ethnic differences in the links among victimization, perceived self-efficacy, and academic achievement, the associations between the latter two constructs were weaker in the minority than the majority samples. We do not have a clear-cut explanation for this finding. It is possible, however, that the weaker associations among the minority students reflect the process of psychological disidentification, which has been found among negatively stereotyped minority groups (Major, Spencer, Schmader, Wolfe, & Crocker, 1998; Steele, 1997). This process involves the disengagement of self-evaluations from academic accomplishments in order to protect one's self-worth. Following the bidirectional link between academic achievement and perceived self-efficacy (see Marsh et al., 2005; Trautwein et al., 2006), one could argue that disidentification works both ways. That is to say, once minority

students detach their perceived self-efficacy from their academic outcomes, these perceptions will have less motivating properties (Marsh et al., 2005; Trautwein et al. 2006; Valentine et al., 2004). Longitudinal studies are needed to test this idea. Irrespective of the exact explanation, the findings further emphasize the usefulness of multiethnic samples in studies of the school adjustment in early adolescent students (see Hanish & Guerra, 2000; Storch et al., 2002).

To evaluate the present research, the reader should consider several qualifications. First, as noted, our design was cross-sectional, and, thus, the possibility of inverse or reciprocal effects cannot be ruled out. Future studies should use longitudinal designs to examine our hypotheses. Still, there are arguments in favor of our interpretation. As mentioned, there are longitudinal findings showing that victimization is more a cause than a consequence of academic achievements (Buhs et al., 2006; Schwartz et al., 2005). Furthermore, there are longitudinal findings showing that academic self-concept influences educational attainment level (Guay et al., 2004). Finally, a set of additional analyses, not reported here, indicated that the link between victimization and perceived self-efficacy was not mediated by students' achievement outcomes. This suggests that if victimization influenced students' academic adjustment, as argued in the present study, it affected students' perceived self-efficacy prior to their actual outcomes.

Second, the study was limited by its reliance on student reports. Whereas the self-report method was adequate for the assessment of academic self-efficacy, self-esteem, and depressed affect, it is possible that the achievement and victimization measures were affected by response bias. Future studies should obtain achievement data from teachers or school records and could assess victimization through sociometric ratings or teacher reports. However, we agree with other researchers that perceptions of victimization should be studied because of phenomenological reasons and their psychological consequences (Graham & Juvonen, 1998). In addition, there is reason to assume that students' reports of their academic achievement were valid and, hence, reliable. Previous research has found that students' self-reported grades were strongly related to their actual GPA (Dornbusch, Ritter, Leiderman, Roberts, & Fraleigh, 1987).

Third, absolute achievement was measured with the students' official secondary educational advice. Research has found that this advice is highly correlated ( $r > .85$ ) with scores on the national standard school achievement test (Driessen & Doesborgh, 2005; Kapinga, 2002). However, the educational advice does not always correspond fully to the score on this test. Differences between educational advice and the test score could be due to the fact that teachers take noncognitive factors into consideration, such as the pupil's motivation and the wishes of the parents and the child (Driessen & Doesborgh, 2005). However, 70% of the variation in the educational advice can be attributed to students' language, math, and reading achievements, and ethnic differences in the educational advice disappear when the effects of these achieve-

<sup>7</sup> Unexpectedly, depressed affect had positive statistical effects on absolute achievement in Tables 3 and 4, and global self-esteem had a negative statistical effect on absolute achievement in Table 3. We do not have an explanation for these findings. However, these statistical effects were small, explaining 0.4%, 0.0%, and 0.5%, respectively, of unique variance.

ment scores are controlled (Driessen & Doesborgh, 2005). Hence, the secondary educational advice appears to be a valid measure of academic achievement.

Fourth, our operationalization of depressed affect was limited. This variable was assessed with three items only yielding a moderate degree of internal consistency. As noted, the unique, negative effects of this measure on students' academic achievement should be interpreted with care. Yet, we think that by including depressed affect in our design, we were able to draw firmer conclusions about the unique mediating role of perceived academic self-efficacy.

Finally, the present study did not consider other potentially important factors that bear upon students' academic achievement. For instance, controlling for students' actual cognitive abilities would have strengthened our conclusions about the mediating role of academic self-efficacy. Future research should examine how victimization affects students' academic adjustment next to, or in interaction with, characteristics such as their abilities, aspects of their home environments, their schools' (instructional) climates, and their relationships with teachers. Still, our finding that victimization had similar statistical effects across different classes and different ethnic groups suggests that its influence is rather uniform.

Despite these limitations, we think that the present study makes a contribution to the literature by examining whether peer-victimized students do less well academically due to self-perceptions of academic incompetence. The findings support the mediating role of perceived self-efficacy. It was found that this role cannot be attributed to general negative self-feelings and is similar for both ethnic minority and majority groups. Experiences of peer victimization appear to have various negative effects for children, including lower academic achievement. Children who have to deal with peer victimization tend to feel academically less competent and thereby miss an important motivation to perform and achieve.

A study of 805 4th through 7th graders used a model of motivational development to guide the investigation of the internal dynamics of 4 indicators of behavioral and emotional engagement and disaffection and the facilitative effects of teacher support and 3 student self-perceptions (competence, autonomy, and relatedness) on changes in these indicators over the school year. In terms of internal dynamics, emotional components of engagement contributed significantly to changes in their behavioral counterparts; feedback from behavior to changes in emotion were not as consistent. Teacher support and students' self-perceptions (especially autonomy) contributed to changes in behavioral components: Each predicted increases in engagement and decreases in disaffection. Tests of process models revealed that the effects of teacher context were mediated by children's self-perceptions. Taken together, these findings suggest a clear distinction between indicators and facilitators of engagement and begin to articulate the dynamics between emotion and behavior that take place *inside* engagement and the motivational dynamics that take place *outside* of engagement, involving the social context, self-systems, and engagement itself.

**Keywords:** academic engagement, disaffection, achievement motivation, classroom participation, emotional engagement

Over the past 10 years, research has converged on the construct of academic engagement as a key contributor to children's school success (Fredricks, Blumenfeld, & Parks, 2004). In the short term, engagement predicts students' learning, grades, and achievement test scores; over the long term, it predicts patterns of attendance, retention, graduation, and academic resilience (Connell, Spencer, & Aber, 1994; Finn & Rock, 1997; Jimerson, Campos, & Greif, 2003; Sinclair, Christenson, Lehr, & Anderson, 2003; Skinner, Zimmer-Gembeck, & Connell, 1998). Studies have also suggested that academic engage-

ment serves as a protective factor against risky activities (O'Farrell & Morrison, 2003) such as substance abuse, risky sexual behavior, and delinquency.

Thus, students who are engaged in school are both more successful academically and more likely to avoid the pitfalls of adolescence. Unfortunately, however, research has also documented a steady decline in students' engagement with schooling, including their interest, enthusiasm, and intrinsic motivation for learning in school, beginning in kindergarten and continuing until they complete high school (or drop out), with notable losses during the transitions to middle school and high school; the erosion of engagement is especially severe for boys and for children from ethnic and racial minority and low socioeconomic status groups (for a review, see Wigfield, Eccles, Schiefele, Roeser, & Davis-Kean, 2006).

We express our gratitude to the Motivation Research Group, especially James Connell, Edward Deci, and Richard Ryan. We would especially like to express our appreciation to James Wellborn for his earlier work on conceptualization and measures of engagement. In terms of the research project, we thank the Brockport School District and its superintendent, principals, teachers, students, and parents for their generous participation. The hard work and good spirits of the research team members are gratefully acknowledged, including Jeff Altman, Michael Belmont, Helen Dorsett, Jennifer Herman, Marianne Miserandino, Brian Patrick, Cara Regan, Hayley Sherwood, and Peter Usinger. We acknowledge support from the W. T. Grant Foundation, from National Institute of Child Health and Human Development Research Grant No. HD19914, and from National Institutes of Mental Health Training Grant No. 527594.

Correspondence concerning this article should be addressed to Ellen A. Skinner, Psychology Department, P.O. Box 751, Portland State University, Portland, OR 97221. E-mail: skinnere@pdx.edu

## Motivational Dynamics of Classroom Engagement and Disaffection

Of great interest to researchers and practitioners are the dynamics underlying these declines. *Dynamics* refers to the internal and external causal feedback loops that serve to promote or undermine the quality of children's engagement in school over time. In general, these dynamics seem to be amplifying, in that children who start out motivationally rich maintain their engagement as the year(s) progress, whereas children who start out motivationally poor tend to become even more disengaged over time (Skinner, Kindermann, Connell, & Wellborn, in press).

Some of these dynamics involve personal motivational resources, such as perceived control: For example, children who start

off confident in their capacities engage with learning tasks in ways that lead to more success, thus reinforcing their initial optimism, whereas children low in efficacy tend to avoid challenges or engage in tasks so half-heartedly that they do not succeed, thereby cementing their initial self-doubts (e.g., Schmitz & Skinner, 1993). Other dynamics involve the teacher: Children who are more engaged receive subsequently more teacher involvement, whereas disaffected children are more likely to find that teachers increasingly withdraw their support or become more controlling over time (e.g., Skinner & Belmont, 1993). It is also possible that some of these dynamics are internal to engagement itself. If multiple components of engagement can be distinguished, they may form their own feedback loops. For example, children who are bored may exert less effort and stop paying attention to the teacher, thus becoming even more bored over time.

Purposes of the Current Study

The current study makes two key contributions to emerging work on motivational dynamics. First, we explore the internal dynamics of engagement by examining how different components of engagement shape each other over time. Second, we explore the larger motivational dynamics of which engagement is a part by examining how contextual and personal factors contribute to changes in engagement itself. Both the components of classroom engagement and the set of facilitators hypothesized to promote them are derived from a larger motivational model, the self-system model of motivational development (SSMMD), which can be used to explain the interpersonal and psychological processes by which engagement is promoted or undermined in the classroom (Connell & Wellborn, 1991; Deci & Ryan, 1985; Skinner & Wellborn, 1997).

Conceptualization of Engagement

Operationalizations of engagement have been offered from a variety of theoretical and practice approaches, leading reviewers to conclude that it is a metaconstruct encompassing multiple dimensions of attraction to or involvement in school (Fredricks et al., 2004). However, two important areas of confusion remain. The first focuses on the distinction between indicators versus facilitators of engagement (Sinclair et al., 2003). *Indicators* refer to the features that belong inside the construct of engagement proper, whereas *facilitators* are the causal factors (outside of the construct) that are hypothesized to influence engagement. Explanatory research and intervention efforts require a clear demarcation between these two. If, for example, conceptualizations posit that support provided by teachers is part of engagement itself (i.e., an indicator) as opposed to a contextual factor that contributes to engagement (i.e., a facilitator), studies that aggregate these features into a metaconstruct can never explore how teacher context shapes children’s engagement. To empirically examine how potential antecedents influence engagement, it is necessary to conceptually unpack indicators from facilitators.

The second issue requiring clarification centers on the number and nature of dimensions within engagement itself: how many should be distinguished and whether they have their own internal dynamics. Some reviewers have suggested that it is useful to distinguish affective, behavioral, and cognitive forms (e.g.,

Fredricks et al., 2004), but little agreement exists as to what these components entail. Others suggest that “good news” should be differentiated from “bad news” features, based on the argument that alienation and disaffection likely reflect more than a lack of engagement (Jimerson et al., 2003). Clear definitions, sound assessments, and evidence of multiple dimensions are required to answer questions about the components of engagement.

Indicators of Classroom Engagement

In this study, we used a motivational conceptualization of engagement versus disaffection, which focuses on students’ active participation in academic activities in the classroom (Pierson & Connell, 1992; Ryan, 2000; Skinner et al., 1998; Wentzel, 1993). The underlying assumption is that high-quality learning is the result of behaviors and emotions, such as exertion, persistence, interest, and enjoyment, that reflect a motivation to master the academic material. As depicted in Figure 1, this conceptualization incorporates behavioral and emotional dimensions, as well as a specific treatment of negative engagement referred to as *disaffection* (Connell & Wellborn, 1991; Skinner, Kindermann, & Furrer, in press; Wellborn, 1991).

The behavioral dimension of engagement includes students’ effort, attention, and persistence during the initiation and execution of learning activities. The emotional dimension of engagement focuses on states that are germane to students’ emotional involvement during learning activities such as enthusiasm, interest, and enjoyment (Meyer & Turner, 2002). Engagement itself combines behavioral and emotional dimensions and refers to active, goal-directed, flexible, constructive, persistent, focused, emotionally positive interactions with the social and physical environments (in this case, academic activities). Consistent with the SSMMD, this kind of engagement has been found to be a strong predictor of

	ENGAGEMENT	DISAFFECTION
B E H A V I O R	<b>Behavioral Engagement</b>	<b>Behavioral Disaffection</b>
	Action initiation	Passivity
	Effort, Exertion	Giving up
	Attempts, Persistence	Withdrawal
	Intensity	Inattentive
	Attention, Concentration	Distracted
	Absorption	Mentally disengaged
E M O T I O N	<b>Emotional Engagement</b>	<b>Emotional Disaffection</b>
	Enthusiasm	Boredom
	Interest	Disinterest
	Enjoyment	Frustration/anger
	Satisfaction	Sadness
	Pride	Worry/anxiety
	Vitality	Shame
	Zest	Self-blame

Figure 1. A motivational conceptualization of engagement and disaffection in the classroom.

student learning, grades, achievement, and school retention (e.g., Connell, Halpern-Fisher, Clifford, Crichlow, & Usinger, 1995; Connell et al., 1994; Skinner, Wellborn, & Connell, 1990).

Disaffection, which signifies more than the absence of engagement, refers to the occurrence of behaviors and emotions that reflect maladaptive motivational states. Disaffection has both a behavioral component, including passivity and withdrawal from participation in learning activities, and an emotional component, including boredom, anxiety, and frustration in the classroom. Disaffection has been found to be a strong predictor of poor grades, low achievement test scores, and eventual drop out (e.g., Connell et al., 1994, 1995; Skinner et al., 1990).

Recent psychometric work has suggested that these four markers of classroom engagement, namely, behavioral and emotional engagement and behavioral and emotional disaffection, are structurally distinguishable (Furrer, Skinner, Marchand, & Kindermann, 2006; Skinner, Kindermann, & Furrer, in press). More specifically, item sets tapping each of the four dimensions were used to directly compare structural models with different numbers of dimensions. Although the dimensions were closely related, a four-factor model showed a significantly better fit to both student- and teacher-report data than either one- or two-factor models. This pattern was found for elementary, middle, and high school students. Evidence of additional (hierarchical) multidimensionality was found for emotional disaffection: Item sets tapping boredom, frustration, and anxiety were better represented by three dimensions than by a single dimension.

### *Internal Dynamics of Engagement and Disaffection*

Although researchers have suggested the importance of deconstructing engagement and examining how the parts work together before combining them into an aggregate or metaconstruct (e.g., Fredricks et al., 2004), theories depicting the internal dynamics of engagement, that is, how the components of engagement mutually influence each other over time, have not been fully articulated. The baseline proposition is that there are none: Behavioral and emotional engagement in the classroom are tightly coupled, largely interindividually stable, and shaped in the same ways by outside factors, without influencing each other. However, when internal dynamics are mentioned, it is usually with the idea that emotions fuel behaviors in the classroom. For example, self-determination theory (Deci & Ryan, 1985) and theories of effectance motivation (Harter, 1978) suggest that it is engaged emotions, such as interest and enthusiasm, that fuel engaged behaviors, such as effort and persistence.

Emotions may also play a leading role in the dynamics of how students lose engagement and become disaffected as the school years progress (e.g., Finn, Pannozzo, & Voelkl, 1995; Roeser, Strobel, & Quihuis, 2002). That is, if students become bored, frustrated, or anxious about schoolwork, this likely undermines their behavioral participation in academic activities. Because the disaffected emotions can be differentiated, it is possible that they may have different effects on behavior. For example, boredom, a relatively passive emotion, might result in losses in behavioral engagement, but perhaps not lead to more overt behavioral disaffection. However, an emotion like frustration might be more strongly linked to active behavioral disaffection in the classroom. Hence, on the basis of recent research that distinguishes four

indicators, the first contribution of the present study was to examine how these components work together over time.

### *Facilitators of Classroom Engagement*

The second goal of the current study was to examine the processes through which an engaged dynamic is created and maintained in the classroom. Hypotheses were drawn from the SSMMD, which focuses on engagement but depicts a larger motivational dynamic (Connell & Wellborn, 1991; Deci & Ryan, 1985). The SSMMD includes four basic higher order constructs: context, self, action, and outcomes (see Figure 2). The general hypothesis, supported by accumulating empirical evidence, is that a more supportive classroom context promotes positive self-perceptions, which in turn fuel engagement in the classroom; conversely, a less supportive classroom context undermines self-perceptions, which then feed disaffection with learning. Empirical support for each of the links posited by the model is described briefly below, with a special focus on differential predictions for behavioral versus emotional engagement.

### *Self-System Processes and Classroom Engagement Versus Disaffection*

Within the SSMMD, self-system processes (SSPs) are defined as relatively durable personal resources (or liabilities) that individuals construct over time in response to interactions with the social context; they are organized around people's basic needs for competence, autonomy, and relatedness. SSPs, within this framework, are proximal predictors of engagement and disaffection. Hence, the SSMMD holds that beliefs about the self can be distinguished from engagement. This distinction is important because in the larger literature on academic engagement, a group of constructs with the common theme of interpersonal relationships (e.g., school attachment, school bonding, and school belonging) has been classified as a dimension of engagement itself (Jimerson et al., 2003). The SSMMD pulls the interpersonal relationship piece out of the definition of engagement and establishes SSPs as facilitators rather than indicators of engagement. Each of the three SSPs has a long history of study under a variety of labels.

*Competence.* Competence is perhaps the most frequently studied self-perception in the academic domain (Wigfield et al., 2006). According to the SSMMD, individuals are born with the need to experience themselves as effective in their interactions with the environment (Elliot & Dweck, 2005; White, 1959), and the extent to which they feel this sense of mastery is related to the quality of their engagement in that domain. Perceptions of self-efficacy, ability, academic competence, and control are robust predictors of children's effort and persistence in school and of their emotional reactions to success and failure (see Bandura, 1997; Dweck, 1999; Elliot & Dweck, 2005; Harter, 1982; Skinner, 1995; Stipek, 2002; Weiner, 2005; Wigfield et al., 2006).

*Autonomy.* Following self-determination theory (Deci & Ryan, 1985), the model holds that individuals are born with the need to express their genuine preferences and act in congruence with their true selves; the extent to which individuals experience autonomy in a particular domain is related to the quality of their engagement in that domain. Studies have generally shown that students with a greater sense of autonomy in school settings have

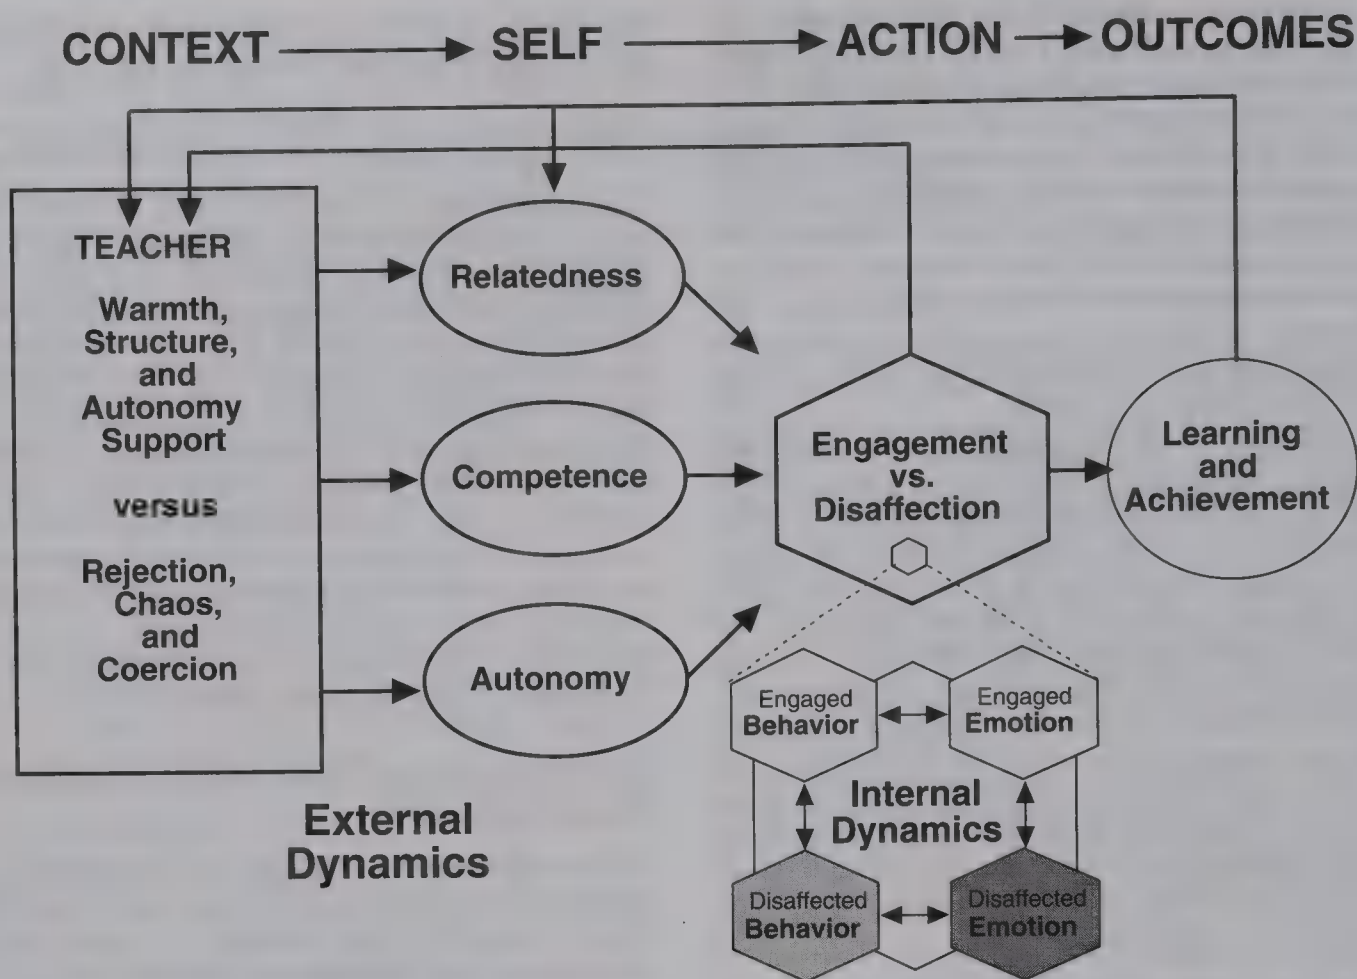

Figure 2. The self-system model of motivational development, including dynamics internal to engagement and external dynamics that incorporate engagement.

better academic outcomes such as classroom engagement, persistence, achievement, and learning (e.g., Grolnick & Ryan, 1987; Hardre & Reeve, 2003; Miserandino, 1996; Patrick, Skinner, & Connell, 1993; Vallerand, Fortier, & Guay, 1997).

**Relatedness.** Relatedness tends to be overlooked as a self-perception in the academic domain. From a motivational perspective, the basic concept is that individuals are born with an innate desire to connect to others (Ainsworth, Blehar, Waters, & Wall, 1978; Bowlby, 1969/1973; Baumeister & Leary, 1995) and that the extent to which they feel that they belong in a particular enterprise is associated with the quality of their engagement in the activities of that enterprise. Research has documented a link between a sense of belonging in school and multiple indicators of academic motivation and adjustment, especially emotional engagement (Anderman, 1999; Anderman & Anderman, 1999; Battistich, Solomon, Watson, & Schaps, 1995; Eccles & Midgley, 1989; Furrer & Skinner, 2003; Goodenow, 1993; Kuperminc, Blatt, Shahar, Henrich, & Leadbetter, 2004; Lynch & Cicchetti, 1997; Roeser, Midgley, & Urdan, 1996; Ryan, Stiller, & Lynch, 1994; Wentzel, 1997, 1998, 1999).

#### *Contextual Supports Shape Classroom Engagement Versus Disaffection*

The SSMMD holds that contextual features are critical in promoting motivation in the classroom (Connell & Wellborn, 1991; Deci & Ryan, 1985; Stipek, 2002; Weiner, 1990). Although students' moti-

vation is shaped by multiple social partners (Wentzel, 1998), the current study targets supportive interactions with teachers. Support for motivation includes pedagogical caring (Wentzel, 1997) as well as autonomy-supportive instruction (e.g., relevance and giving students choices; Guthrie & Davis, 2003; Reeve, Bolt, & Cai, 1999; Reeve, Jang, Carrell, Jeon, & Barch, 2004) and optimal structure (e.g., predictability and responsiveness; Skinner et al., 1998). The quality of student-teacher relationships, in the form of caring, supportive alliances, is a key predictor of academic engagement, effort in the classroom, school liking, and achievement expectancies (Birch & Ladd, 1997, 1998; Goodenow, 1993; Murdock, 1999; Murray & Greenberg, 2000; Ryan & Powelson, 1991).

*SSPs mediate the relationship between context and classroom engagement.* Finally, the SSMMD also posits a specific mediated pathway in which features of the context influence how individuals feel about themselves (i.e., SSPs), which in turn predicts whether they will be engaged or disaffected in that context. Fredricks et al. (2004), in their review of the construct of engagement, noted that "few scholars include measures of context, needs, and engagement in the same study" (p. 80). One study that did test mediated pathways between context and engagement showed that positive student-teacher relationships were connected to a sense of school belonging, which in turn predicted positive affect in school (Roeser et al., 1996). The current study addresses this empirical gap by testing a mediated pathway from teacher support to self-perceptions to engagement versus disaffection.

### Summary of Hypotheses

In sum, on the basis of a clear distinction between indicators and facilitators of engagement, we aimed to examine some of the dynamics underlying the general decline in motivation during late elementary and early middle school. Using information collected from fourth through seventh graders at the beginning and end of the same school year, we first attempted to replicate the pattern of between-year differences and within-year decrements in engagement that suggest general motivational losses over the transition to middle school. Second, we examined the dynamics between emotion and behavior that take place inside engagement, testing the hypothesis that not only would behavior predict changes in emotion, but that emotion would be an even stronger predictor of changes in behavior. We further decomposed emotional disaffection into a set of multiple indicators (frustration, boredom, and anxiety) to examine whether they played a differential role in predicting changes in the other facets of engagement.

Third, we examined the motivational dynamics that take place outside of engagement, involving the social context, self-systems, and engagement itself. We predicted that children's SSPs would contribute to changes in their engagement over the school year, with perceived competence being perhaps the biggest predictor of changes in behavior and relatedness and autonomy being stronger predictors of changes in emotion. Moreover, we expected teacher support to predict changes in student engagement and disaffection, with SSPs representing an important pathway through which teachers' support would be connected to engagement. Although we expected mean-level differences in engagement according to gender and grade (favoring girls and younger children), we nevertheless hypothesized that the dynamics of engagement would not differ among these groups. In sum, the present study has the potential to help organize conceptualizations of the complex multidimensional construct of engagement and to contribute to ongoing research that examines the social and personal factors that shape its development over time.

### Method

#### Participants

Data from 805 children (195 fourth graders, 131 fifth graders, 290 sixth graders, and 189 seventh graders approximately equally divided by gender) who had participated in a 4-year longitudinal study on children's motivation in school were used from two measurement points (fall and spring of Year 4). Students and their 53 teachers, drawn from the only public elementary and middle schools in a rural-suburban school district in upstate New York, were predominantly Caucasian, with only about 5% of the students identifying themselves as non-White. Student socioeconomic status, as determined by parents' level of education and occupation, ranged between working to middle class. (See Skinner et al., 1998, for details.) From the 1,242 children who provided any data during Year 4, we selected a subset of 805 children who were missing less than 5% of their data. For this subsample, missing data were imputed with SPSS 11.5 using maximum likelihood estimation with an estimation maximization algorithm.

#### Procedures

Students completed self-report questionnaires administered by trained interviewers in three 45-min sessions. In their normal class-

rooms, students marked questionnaire items as they were read aloud by one interviewer; a second interviewer monitored understanding and answered questions. Teachers were not present; for the most part, they filled out their questionnaires while students were being tested. Questionnaires were administered in October and again in May.

### Measures

Students reported on their engagement versus disaffection in the classroom, their sense of perceived competence and control in the academic domain, autonomy in the classroom, and relatedness to their teacher and their impressions of the support they received from teachers. Teachers reported on the support they provided to each student. If a student had multiple teachers, information was provided from the teacher who indicated that he or she knew the student the best. Each scale was made up of positively and negatively worded items. Composite scores were determined by calculating the average of the positive and negative items, then reverse coding the negative subscale and averaging it with the positive subscale. Resulting scores ranged from 1 to 4, with higher scores indicating more of the respective construct.

*Behavioral and emotional engagement and disaffection.* Students reported on their own engagement versus disaffection in the classroom using a measure developed to tap their behavioral and emotional participation in (or withdrawal from) learning activities in the classroom (Skinner et al., 1990, 1998; Wellborn, 1991). Behavioral engagement was assessed using 5 items that tapped students' effort, attention, and persistence while initiating and participating in learning activities ( $\alpha = .71$  in fall;  $\alpha = .72$  in spring). Behavioral disaffection was assessed using 5 items that tapped students' lack of effort and withdrawal from learning activities ( $\alpha = .65$  in fall;  $\alpha = .70$  in spring). Emotional engagement was measured using 6 items that tapped emotions indicating students' motivated participation during learning activities ( $\alpha = .83$  in fall;  $\alpha = .84$  in spring). Emotional disaffection was measured using 10 items that tapped emotions indicating students' motivated withdrawal or alienation during learning activities. Items were averaged according to the specific emotions (boredom, anxiety, and frustration) and then combined for a summary score ( $\alpha = .84$  in fall;  $\alpha = .84$  in spring). Items from the current version of the student-report measure are presented in the Appendix. (See also Skinner, Kindermann, & Furrer, in press.)

*Perceived competence and control.* The Control Beliefs subscale of the Student Perceptions of Control Questionnaire (Skinner, Chapman, & Baltes, 1983, 1988; Skinner et al., 1990) was used to tap children's perceived competence. The Control Beliefs subscale consists of six items tapping students' generalized expectancies about the extent to which they can achieve success and avoid failure in school. Examples of items are "I can do well in school if I want to" and "I can't get good grades, no matter what I do" (reverse coded; Skinner et al., 1990, 1998). Items were averaged to form a summary score ( $\alpha = .74$  in fall;  $\alpha = .73$  in spring).

*Autonomy orientation.* The Autonomy Scale, used to assess academic autonomy (Ryan & Connell, 1989), is composed of 17 items that tap whether children engage in activities because they feel pressured or because they desire understanding and enjoy the task, divided into four subscales: (a) External self-regulation refers to doing work because of rules or fear of punishment ("Why do I do my homework? Because I'll get in trouble if I don't"); (b)

introjected self-regulation refers to doing work because one "should" and to avoid negative emotions ("Because I'll feel really bad about myself if I don't do well"); (c) identified self-regulation refers to doing work to understand more ("Because I think class-work is important for my learning"); and (d) intrinsic self-regulation refers to doing work because it is enjoyable ("Because it's fun"). Subscales for external and introjected self-regulation were reverse coded and then averaged with subscales for identified and intrinsic self-regulation to form a summary score ( $\alpha = .81$  in fall;  $\alpha = .81$  in spring).

**Sense of relatedness.** Students completed a four-item self-report scale tapping a sense of belonging or relatedness to their teachers (Furrer & Skinner, 2003). For each item, the stem was "When I'm with my teacher" and the items were "I feel accepted," "I feel like someone special," "I feel ignored" (reverse coded), and "I feel unimportant" (reverse coded). The items were averaged to form a summary score ( $\alpha = .82$  in fall;  $\alpha = .84$  in spring).

**Teacher support: Student report.** Students reported on the involvement, structure, and autonomy support they experienced from their teachers (Skinner & Belmont, 1993). Nine items tapped involvement versus hostility, including warmth-affect, dedication of resources, knowledge about the student, and dependability versus hostility and neglect (reverse coded). Example items include "My teacher likes me" and "My teacher doesn't seem to enjoy having me in her class" (reverse coded). Twenty-one items measured provision of structure, including clarity of expectations and contingency, versus chaos (reverse coded). Example items are "My teacher shows me how to solve problems for myself" and "My teacher doesn't make clear what she expects of me in class" (reverse coded). Eighteen items tapped autonomy support versus coercion, including teacher provision of choice, relevance, and respect versus controlling behavior (reverse coded). Example items are "My teacher gives me a lot of choices about how I do my schoolwork" and "It seems like my teacher is always telling me what to do" (reverse coded). Scales were averaged to form a Teacher Support scale ( $\alpha = .96$  in fall;  $\alpha = .96$  in spring).

**Teacher support: Teacher report.** Teachers reported on the level of involvement, structure, and autonomy support they pro-

vided to each child (Skinner & Belmont, 1993). Fourteen items tapped involvement versus hostility, including warmth-affect, dedication of resources, knowledge about the student, and dependability versus hostility and neglect (reverse coded). Example items include "This student is easy to like" and "Teaching this student is not very enjoyable" (reverse coded). Five items measured provision of structure, including clarity of expectations and contingency, versus chaos (reverse coded). Example items are "I try to be clear with this student about what I expect of him/her in class" and "I find it hard to be consistent with this student" (reverse coded). Twelve items tapped autonomy support versus coercion, including teacher provision of choice, relevance, and respect versus controlling behavior (reverse coded). Example items are "I let this student make a lot of his/her own decisions regarding schoolwork" and "When it comes to assignments, I'm always having to tell this student what to do" (reverse coded). Scales were averaged to form a Teacher Support scale ( $\alpha = .95$  in fall;  $\alpha = .95$  in spring).

## Results

Initial analyses examined descriptive information. As can be seen in Table 1, indicators of engagement versus disaffection suggested that averaged over fall and spring, students were moderately engaged ( $M = 3.21$ ,  $SD = 0.50$ , for behavioral and emotional engagement combined) and not particularly disaffected ( $M = 2.07$ ,  $SD = 0.57$ , for behavioral and emotional disaffection combined). In terms of facilitators, children reported relatively high levels of all three self-systems averaged over fall and spring, although they reported higher competence ( $M = 3.44$ ,  $SD = 0.49$ ) than relatedness ( $M = 3.03$ ,  $SD = 0.69$ ) and higher relatedness than autonomy ( $M = 2.58$ ,  $SD = 0.45$ ). In addition, teachers were perceived as supportive ( $M = 2.95$ ,  $SD = 0.52$ ) and themselves reported providing relatively high support ( $M = 3.15$ ,  $SD = 0.38$ ).

### Grade Differences and Changes in Engagement and Disaffection

To determine whether we could replicate the pattern of between-grade differences and within-grade declines indicating losses in

Note.  $N = 805$ . All scales ranged from 1 (not at all true for me/this student) to 4 (very true for me/this student).

\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

motivation over the transition to middle school, we first examined each indicator and facilitator as a function of grade; see Table 2 for means and standard deviations (averaged across the two time points). As is typical (Fredricks et al., 2004; Wigfield et al., 2006), starting in sixth grade (during the transition to middle school), older children showed lower levels of engagement and higher levels of disaffection. Profile analyses, in which the four indicators of engagement were used as within-subject dependent variables, indicated that the profiles of engagement differed by grade,  $F(12, 2111) = 8.64, p < .001$ . As depicted in Figure 3, children in fourth and fifth grades showed a profile in which engagement was high and disaffection was low. However, after the transition to middle school, students showed lower levels of engagement, especially emotional engagement, and higher levels of disaffection, especially emotional disaffection, and this trend continued to worsen in seventh grade. In addition, older children showed lower levels of self-systems and (both teacher- and student-reported) teacher support, with the most noticeable differences starting in middle school between fifth and sixth and between sixth and seventh grades.

Consistent with these differences between grades, there was also a slight worsening in both indicators and facilitators of engagement within grades, in that engagement decreased and disaffection increased from fall to spring, and self-systems and teacher support declined (see Table 1). At the same time, interindividual stability was high: Cross-year correlations for student-report variables averaged .68 (all  $ps < .001$ ). This pattern of findings, namely high interindividual stability combined with motivational declines that are experienced differentially depending on initial levels of engagement, are consistent with the typical amplifying pattern of loss whose underlying dynamics this study was designed to illuminate.

**Gender differences.** Table 2 also presents the means and standard deviations for each indicator and facilitator (averaged across the two time points) broken down by gender. As is typical (Fredricks et al., 2004; Wigfield et al., 2006), mean-level differ-

ences favored girls, although there were no differences in emotional disaffection or any of the differentiated disaffected emotions. In each of the following analyses, we also examined interactions with grade and gender. In no case were they significant, suggesting that despite mean-level differences favoring younger children and girls, the dynamics of engagement played out in a similar manner across fourth through seventh grades and for the boys and girls in this sample.

### *Internal Dynamics Among Indicators of Engagement Versus Disaffection*

The second set of analyses examined the internal dynamics of engagement and disaffection. As can be seen in Table 3, the four indicators showed the expected concurrent interrelations. (See Skinner, Kindermann, & Furrer, in press, for supporting evidence from confirmatory structural analyses.) To test hypotheses about predictors of change over the school year, we calculated multiple regressions in which we controlled for the dependent variable in the fall before examining whether the independent variable in fall was a significant predictor of the dependent variable in spring.

**Emotions as predictors of changes in behavioral engagement.** Figure 4 depicts the regressions that examined whether emotional engagement predicted changes in behavioral engagement and behavioral disaffection. As expected, despite the high stabilities of the dependent variables, emotional engagement in the fall significantly predicted improvements in behavioral engagement and declines in behavioral disaffection from fall to spring.

The top panel of Figure 4 also depicts the regressions testing whether emotional disaffection predicted changes in behavioral engagement and disaffection. As can be seen, emotional disaffection in the fall contributed significantly to increases in behavioral disaffection and decreases in behavioral engagement from fall to spring. Regressions examining the differentiated disaffected emo-

*Note.* Grade means with the same subscripts did not differ from each other at least at the  $p < .05$  level as identified with post hoc tests using the Bonferroni correction.

\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

Figure 3. Grade differences in the four components of behavioral and emotional engagement and disaffection.  
 Note. Solid black lines indicate adjacent grade levels that do not differ significantly at least at the  $p < .05$  level.  
 Dotted black lines indicate adjacent grade levels that do differ significantly at least at the  $p < .05$  level.

tions (bored, anxious, or frustrated) revealed they were significant predictors. Each predicted declines in behavioral engagement (bored,  $\beta = -0.23$ ; anxious,  $\beta = -0.10$ ; and frustrated,  $\beta = -0.12$ ,  $ps < .001$ ) and increases in behavioral disaffection (bored,  $\beta = 0.18$ ; anxious,  $\beta = 0.08$ ; and frustrated,  $\beta = 0.09$ ,  $ps < .01$ ).

**Behavior as a predictor of changes in emotional engagement.** The bottom panel of Figure 4 presents the results of regressions examining whether behavioral engagement in the classroom predicts changes in emotional engagement and disaffection over the school year. As can be seen, behavioral engagement in the fall was a significant predictor of increases in emotional engagement. However, it was not a significant predictor of declines in emotional disaffection. Regressions examining behavioral engagement as a predictor of changes in the differentiated negative emotions revealed that it was a significant predictor of declines in boredom ( $\beta = -0.08$ ,  $p < .01$ ) but not in anxiety or frustration.

The bottom panel of Figure 4 also presents the results of the regressions examining whether behavioral disaffection in the classroom contributes to changes in emotion. As expected, despite the high stabilities of the dependent variables, behavioral disaffection in the fall significantly predicted declines in emotional engagement and increases in emotional disaffection from fall to spring. Regressions examining behavioral disaffection as a predictor of changes in the differentiated negative emotions revealed that

it was a significant predictor of increases in each (bored,  $\beta = 0.12$ ; anxious,  $\beta = 0.14$ ; and frustrated,  $\beta = 0.12$ ,  $ps < .001$ ).

**Feedforward and feedback effects.** To determine whether, as predicted, emotion had stronger feedforward effects on behavior compared with the feedback effects of behavior on emotion, analyses directly compared the coefficients for each pair of predictors and outcomes by subtracting the unstandardized regression coefficients and dividing them by the pooled standard error. Only one pair was significantly different: The regression coefficient depicting the feedforward effect of emotional engagement on changes in behavioral engagement (.24) was significantly greater than the coefficient depicting the feedback effect of behavioral engagement on changes in emotional engagement (.10,  $t = 2.90$ ,  $p < .01$ ). Contrary to predictions, however, for disaffection the feedforward effects of emotion on behavior were not stronger than the feedback effects of behavior on emotion.

#### Potential Facilitators of Engagement: SSPs

The third set of analyses focused on self-perceptions as potential facilitators of engagement. Concurrent correlations among the four indicators of engagement and three SSPs within the two time points appear in Table 4. As can be seen, all were in the predicted direction and significant at  $p < .001$ . To examine predictors of

Table 3  
 Correlations Among the Indicators of Engagement

Construct	1	2	3	4	5	6	7
1. Behavioral engagement	—	-.50	.60	-.35	-.43	-.23	-.21
2. Behavioral disaffection	-.44	—	-.42	.56	.52	.55	.42

4. Emotional disaffection	-.36	.55	-.53	—	(.72)	(.87)	(.85)
5. Bored	-.44	.52	-.54	(.73)	—	.39	.46
6. Anxious	-.25	.47	-.36	(.86)	.40	—	.68
7. Frustrated	-.21	.39	-.38	(.84)	.46	.64	—

Note.  $N = 805$ . Correlations between variables within the Fall time point are below the diagonal. Correlations between variables within the Spring time point are above the diagonal. Correlations in parentheses are between subscale and total scale scores. All correlations are significant at  $p < .001$ .

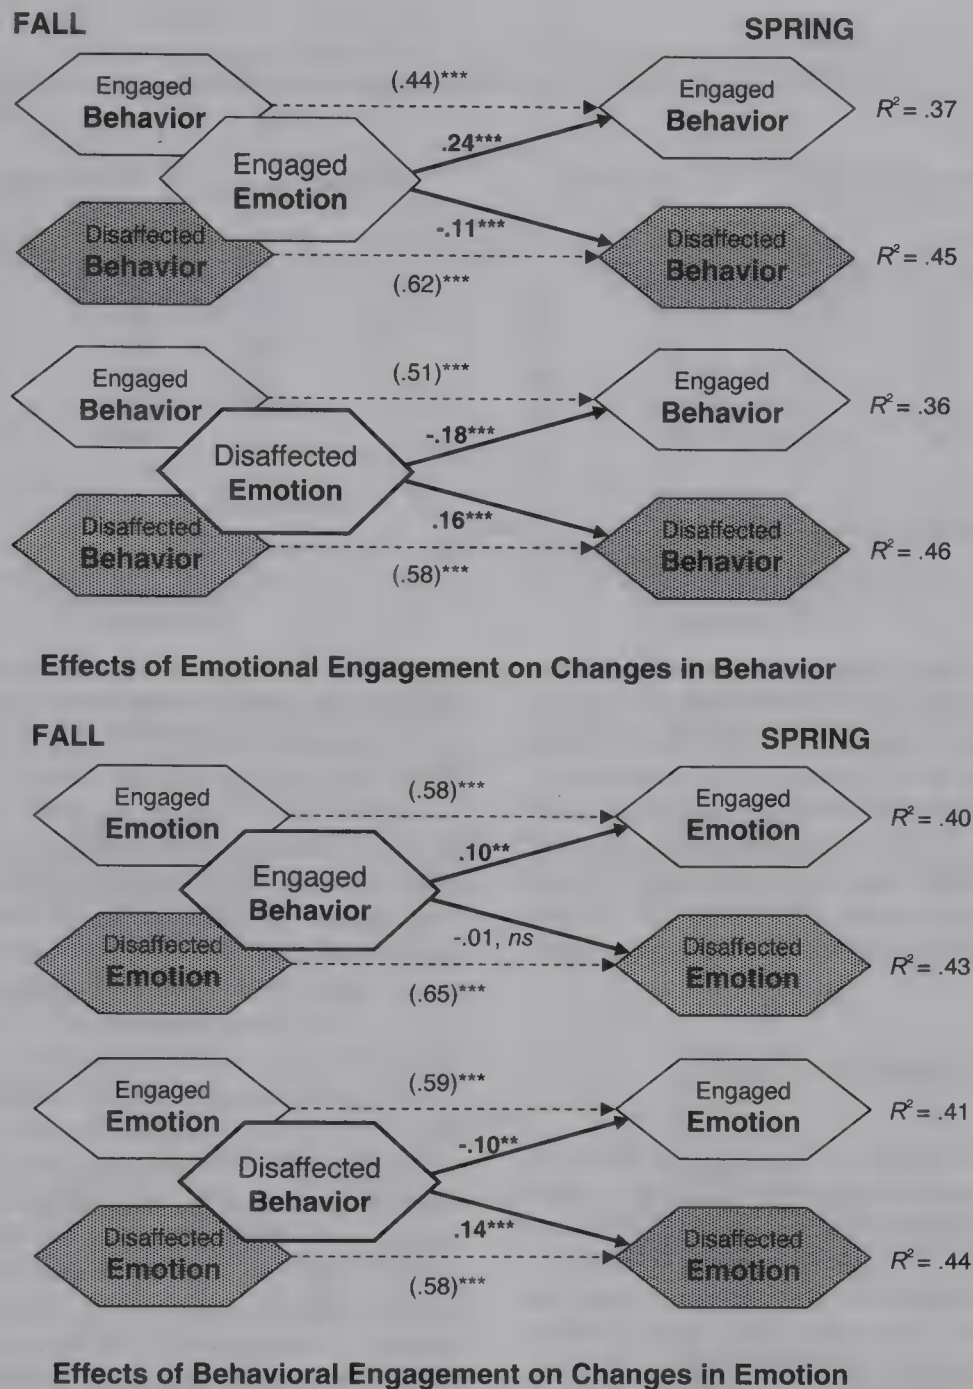

Figure 4. Results of regressions examining the internal dynamics of engagement. Top panel depicts the effects of emotional engagement and disaffection in the fall on changes in behavioral engagement and disaffection from fall to spring. Bottom panel depicts the effects of behavioral engagement and disaffection in the fall on changes in emotional engagement and disaffection from fall to spring.

Note. Standardized regression coefficients are on the solid arrows. Stability correlations from fall to spring are in parentheses.  $**p < .01$ .  $***p < .001$ .

change over the school year, we calculated multiple regressions in which we controlled for the dependent variable in the fall before examining whether the independent variable in fall predicted the dependent variable in spring.

*Self-systems as predictors of behavioral engagement and disaffection.* Figure 5 depicts the results of regressions examining whether SSPs contribute to changes in engagement and disaffection. As can be seen in the top panel, which presents their effects on the behavioral indicators, despite the high stabilities of the dependent variables, each self-system in the fall was a significant predictor of improvements in behavioral engagement and declines

in behavioral disaffection over the school year. Autonomy appeared to be the strongest predictor of change.

*Self-systems as predictors of emotional engagement and disaffection.* As shown in the bottom panel of Figure 5, despite the high stabilities of the emotional indicators, each self-system in the fall was a significant predictor of increases in emotional engagement over the year; again, autonomy was the strongest predictor. For emotional disaffection, however, autonomy was the only significant predictor of declines; despite robust concurrent correlations, neither relatedness nor perceived control were significant predictors of decreases in this indicator. Exploratory analyses ex-

\*  $p < .05$ .

amined whether certain SSPs were stronger predictors of changes in the different disaffected emotions. We were particularly interested in whether children low in autonomy were at risk for increased boredom, whereas students with low perceived control might grow more anxious as the year progressed. Both relatedness ( $\beta = -0.08$ ,  $p < .05$ ) and autonomy ( $\beta = -0.12$ ,  $p < .001$ ) were significant predictors of decreases in boredom. However, perceived control was the only significant predictor of changes in anxiety ( $\beta = -0.08$ ,  $p < .05$ ), and autonomy was the only significant predictor of changes in frustration ( $\beta = -0.15$ ,  $p < .001$ ).

#### Potential Facilitators of Engagement: Teacher Supportive Context

The fourth set of analyses focused on the social facilitators of engagement. Both student reports of their interactions with teachers and teacher reports of their interactions with individual students were used as markers of the support provided by teachers. Correlations between the two markers of teacher support and the four indicators of engagement at two time points appear in Table 4. As can be seen, all were in the predicted direction and were generally significant at  $p < .001$ . Because engagement was also reported by students, student reports of teacher support were much more highly correlated with all indicators of engagement (average  $r = 1.531$ ) than were teacher reports of teacher support (average  $r = 1.171$ ). It is also possible that student reports reflect the more powerful causal influence because it is likely that students' perceptions of their interactions with teachers are the proximal causes of their motivational reactions. It should be noted that student and teacher reports of teacher support were positively correlated at both time points ( $r = .23$  in fall and  $r = .22$  in spring), indicating that despite differences in perspective and developmental level, the two reporters' assessments converged somewhat. Although few studies have examined cross-reporter consistency in perceptions of teacher support, the correlations found in the present study are within the typical range (e.g., Skinner & Belmont, 1993).

*Teacher support as a predictor of changes in engagement.* To examine whether teacher support contributed to changes in student engagement, we calculated two sets of multiple regressions in which either teacher or student reports of teacher support in fall were used to predict each of the indicators of engagement in spring, controlling for

that indicator in fall. Results for student reports of teacher support are depicted in Figure 6: In the top panel are findings for the regressions in which changes in behavioral indicators were the criterion; in the bottom panel are the results for changes in the emotional indicators. As expected, student reports of teacher support predicted improvements in emotional and behavioral engagement and declines in behavioral and emotional disaffection over time. In regressions examining whether teacher support had differential effects on the disaggregated disaffected emotions, we found that student reports of teacher support in fall predicted declines in both boredom ( $\beta = -0.14$ ,  $p < .001$ ) and frustration ( $\beta = -0.09$ ,  $p < .001$ ) from fall to spring; it did not predict changes in anxiety.

The findings for teacher reports of teacher support, although contrary to expectations, were not surprising, considering the strong cross-time stabilities of indicators of engagement and the modest concurrent correlations between teacher reports of teacher support and student-reported engagement. Changes in only one indicator of engagement were predicted by teacher reports of teacher support, namely, behavioral engagement ( $\beta = 0.07$ ,  $p < .05$ ). Consistent with findings for student reports, teacher reports indicated that students who received more teacher support in the beginning of the school year were likely to show improvements in their effort, attention, and persistence in the classroom as the year progressed.

#### Process Models of Potential Facilitators of Engagement

The final sets of analyses examined process models of the facilitators of engagement, in which actual teacher support (captured by teacher reports of teacher support) predicted changes in engagement by shaping students' perceptions of teacher support (captured by student reports of teacher support), which in turn contributed to children's feelings of competence, autonomy, and relatedness, which were themselves the proximal predictors of engagement. A mediated model posits that there would be no significant direct paths from either marker of teacher support to any indicator of engagement. We examined the two parts of the mediator models separately, using the four-step procedure recommended by Baron and Kenny (1986).

*Student experiences of teacher support as mediators of the effects of actual teacher support on changes in engagement.*

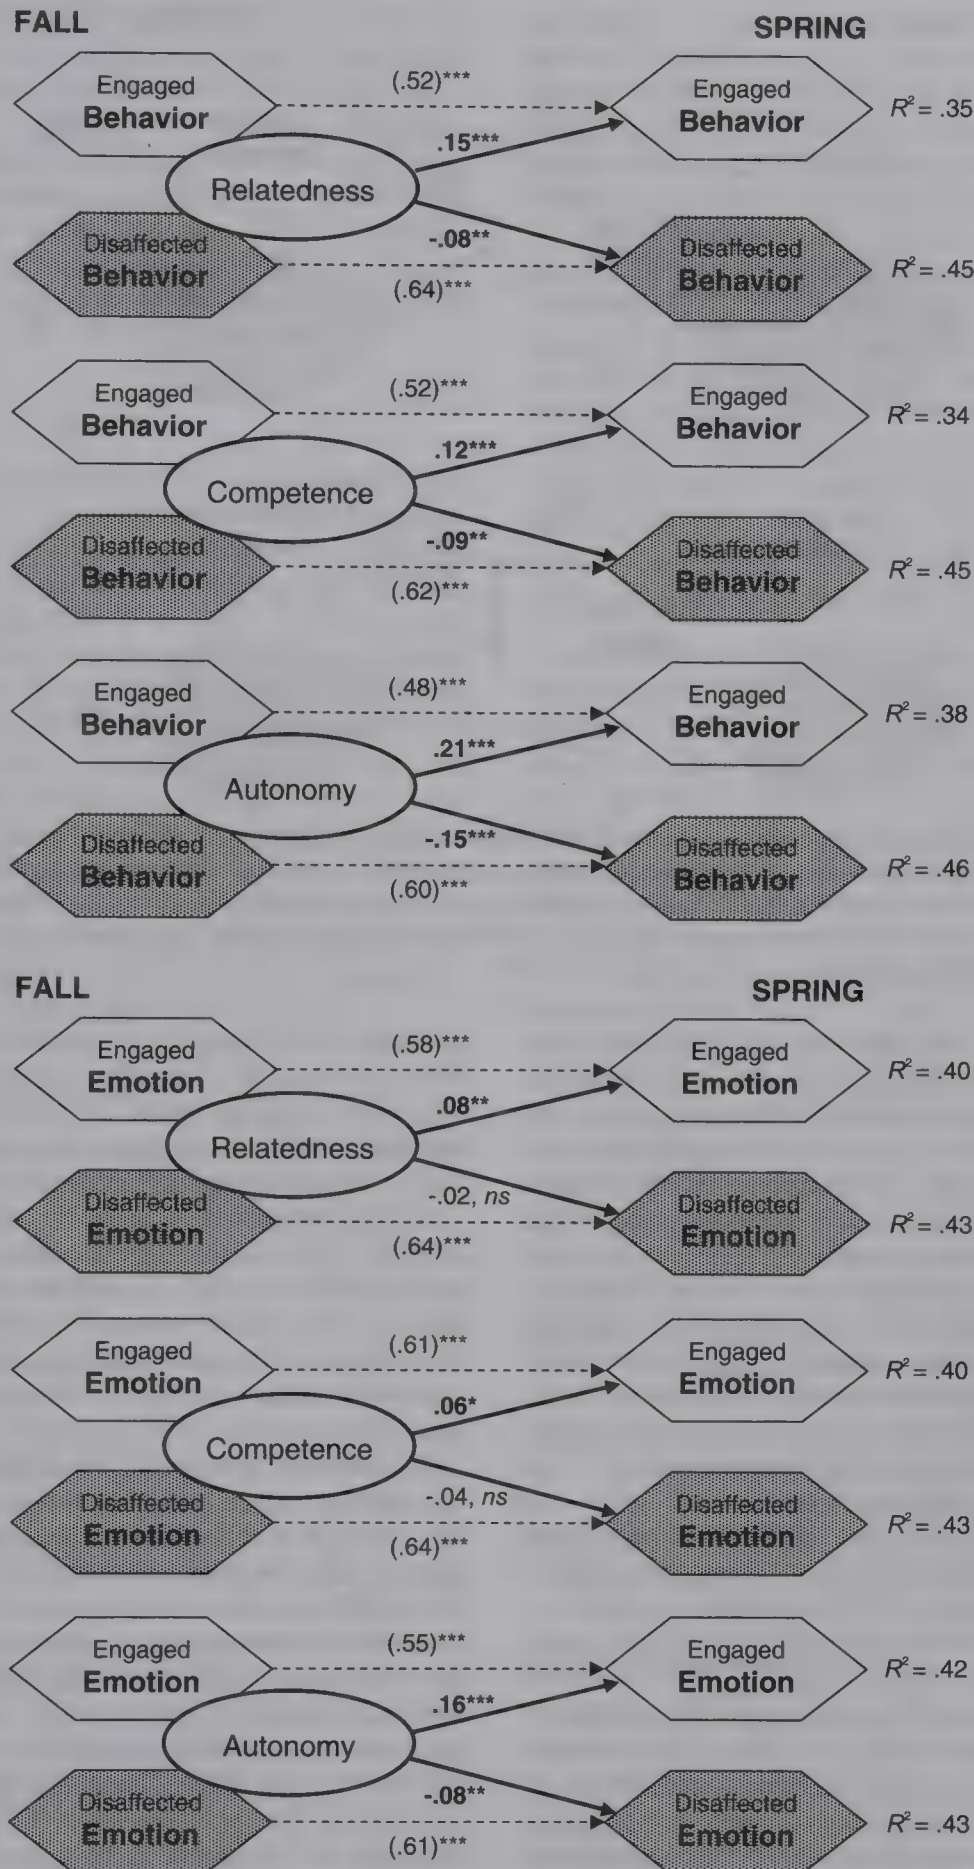

Figure 5. Results of regressions examining the effects of relatedness, competence, and autonomy in the fall on changes in engagement and disaffection from fall to spring. The top panel depicts changes in behavioral engagement and disaffection. The bottom panel depicts changes in emotional engagement and disaffection. Note. Standardized regression coefficients are on the solid arrows. Stability correlations from fall to spring are in parentheses. \*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

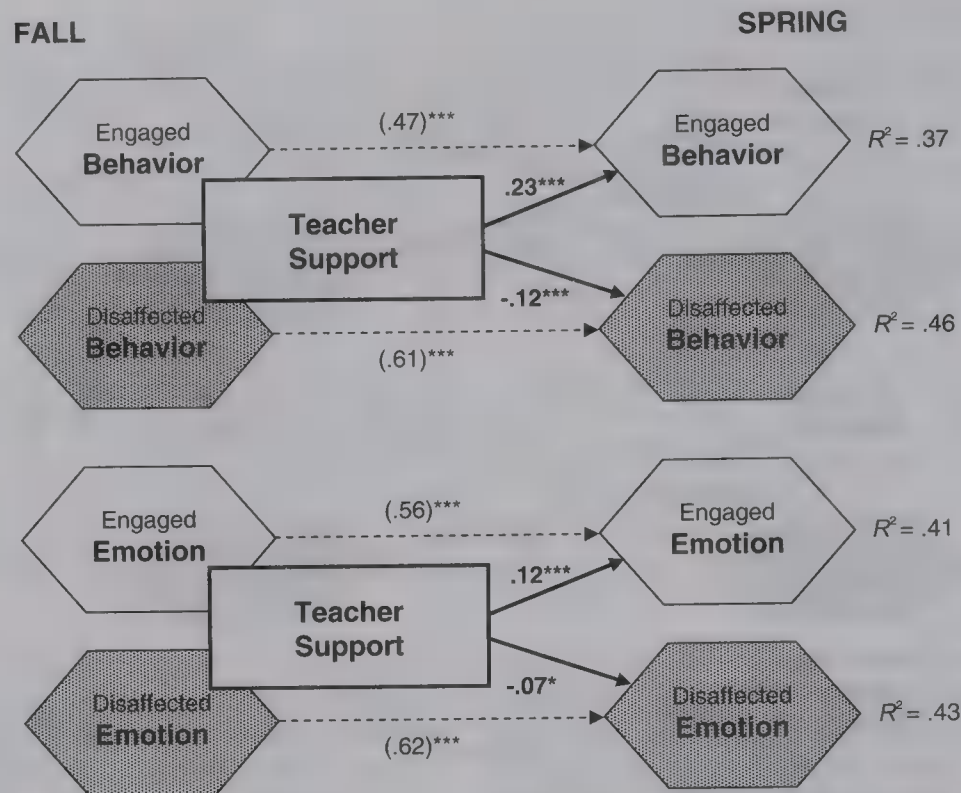

Figure 6. Results of regressions examining the effects of teacher support (student report) in the fall on changes in engagement and disaffection from fall to spring. The top panel depicts changes in behavioral engagement and disaffection. The bottom panel depicts changes in emotional engagement and disaffection. Note. Standardized regression coefficients are on the solid arrows. Stability correlations from fall to spring are in parentheses. \*  $p < .05$ . \*\*\*  $p < .001$ .

First, we explored whether the effects of actual teacher support (marked by teacher reports) on changes in behavioral engagement were mediated by students' perceptions of their interactions with teachers. Preliminary conditions for testing this model were met, namely, that the antecedent (i.e., teacher report of teacher support) was correlated with both (a) the outcome (i.e., changes in behavioral engagement) and (b) the proposed mediator (i.e., student report of teacher support) and that the proposed mediator was correlated with the outcome. The step of most interest was whether, in a regression using both the antecedent and the mediator as independent variables to predict the outcome, the unique effect of the mediator would remain significant, whereas the unique effect of the antecedent would be significantly reduced (indicating partial mediation) or no longer reach significance (indicating full mediation).

The model revealed full mediation. The effects of teacher report of teacher support on changes in behavioral engagement ( $\beta = 0.07, p < .05$ ) dropped substantially when student perceptions of teacher support were added to the equation and were no longer significant ( $\beta = 0.04, ns$ ), whereas student report of teacher support continued to be a significant unique predictor of changes in behavioral engagement ( $\beta = 0.22, p < .001$ ). This pattern of findings is consistent with the idea that teacher support shapes changes in students' behavioral engagement through its effects on children's perceptions of the support teachers provide. Mediational models for the other three indicators of engagement could not be tested because teacher report of teacher support was not a significant predictor of changes in any of them.

*Children's SSPs as mediators of the effects of teacher support on changes in engagement.* Second, we explored whether the effects of students' perceptions of teacher support on changes in the

four indicators of engagement were themselves mediated by students' SSPs of relatedness, competence, and autonomy. For these analyses, we created an aggregate marker by averaging the three SSPs together and followed the same procedures as in the last set of mediational models. Each model focused on changes in one indicator of engagement. For behavioral engagement, the models revealed partial mediation: The effect of teacher support on changes in behavioral engagement ( $\beta = 0.23, p < .001$ ) dropped substantially when the self-system aggregate was added to the equation, but it still remained significant ( $\beta = 0.13, p < .05$ ). As expected, the combined SSPs continued to be a significant unique predictor of changes in behavioral engagement ( $\beta = 0.15, p < .01$ ).

For emotional engagement, the models revealed full mediation: The effect of teacher support on changes in emotional engagement ( $\beta = 0.12, p < .001$ ) dropped substantially when the self-system aggregate was added to the equation and was no longer significant ( $\beta = 0.03, ns$ ), whereas the combined SSPs continued to be a significant unique predictor of changes in emotional engagement ( $\beta = 0.14, p < .001$ ). Similarly, the models for behavioral disaffection also revealed full mediation: The effect of teacher support on changes in behavioral disaffection ( $\beta = -0.12, p < .001$ ) dropped substantially when the self-system aggregate was added to the equation and was no longer significant ( $\beta = -0.04, ns$ ), whereas the combined SSPs continued to be a significant unique predictor of changes in emotional engagement ( $\beta = -0.12, p < .001$ ).

For emotional disaffection, neither predictor remained significant when the other variable was entered in the model: The effects of teacher support on changes in emotional disaffection ( $\beta = -0.07, p < .001$ ) was no longer significant when the aggregate self-systems were added to the equation ( $\beta = -0.06, ns$ ), but

neither were the effects of the combined SSPs ( $\beta = -0.02$ , *ns*). Because each variable was a significant predictor of changes in emotional disaffection when considered alone, the lack of significant unique effects can be attributed to multicollinearity. Taken together, these models suggest that teacher support has an effect on student engagement by shaping students' feelings of relatedness, competence, and autonomy. At the same time, teacher support (at least as perceived by students) also shows a direct effect on behavioral engagement, over and above that of the SSPs assessed in this study.

## Discussion

Guided by a motivational model, this study organized data on indicators and facilitators of engagement collected at the beginning and end of the school year to begin answering questions about the motivational dynamics of engagement. Consistent with other research on engagement (Fredricks et al., 2004; Wigfield et al., 2006), the developmental pattern found in this study, consisting of cross-year declines and age differences favoring younger children, reveal that although these students were relatively engaged, they nevertheless were experiencing losses in engagement and increases in disaffection over the transition to middle school. At the same time, the high cross-year stabilities indicate that children were losing ground commensurate with their initial levels of motivation. Systematic analyses of change over time suggest that this pattern may be fueled by the internal dynamics of engagement and by the larger motivational dynamics of which engagement, along with self-systems and teacher support, is a part.

### *Emotional Dynamics of Engagement*

Consistent with models of self-determination (Deci & Ryan, 1985), effectance motivation (Harter, 1978), and burgeoning interest in the role of emotions in the classroom (e.g., Pekrun, Goetz, Titz, & Perry, 2002; Schutz & DeCuir, 2002), findings from this study revealed positive emotions as one possible driver of children's effortful involvement in learning activities. At the same time, emotional disaffection, especially boredom, seemed to exert a significant downward pressure on children's effort and persistence and predicted their withdrawal from academic tasks. This pattern of findings underscores the idea that when children find learning activities interesting, fun, and enjoyable, they will pay more attention and try harder. However, the time lag from the beginning to the end of the school year suggests that this is more than a short-term gain. Children who are more emotionally engaged in fall show increasing behavioral engagement and declines in behavioral disaffection over the course of the whole year. By the same token, when children have lost their emotional enjoyment and interest in learning, they are not able to sustain behavioral participation in academic activities over time.

### *Behavioral Dynamics of Engagement*

The role of behavior in reciprocally shaping emotion was not as pronounced. Higher levels of effortful involvement in fall were not strong predictors of increases in emotional engagement, and they were not effective in staving off overall emotional disaffection, although they did predict declines in boredom when considered

separately. Behavioral disaffection, which in this study was marked by avoidance and withdrawal of effort, did seem to undermine the development of positive emotions and feed into increases in boredom, anxiety, and frustration. It makes sense that children with low classroom participation will eventually lose their enjoyment of learning activities and become more bored, anxious, and frustrated as the year progresses, whereas children who try hard and persist in learning activities will tend to find them increasingly more fun and enjoyable. However, it is unfortunate that such sustained involvement does not seem to pay off in reductions in anxiety or frustration over the long haul. This suggests that educators' efforts to increase behavioral engagement in ways that do not engage positive emotions may not have the intended lasting effect on children's high-quality participation in learning activities.

### *Larger Motivational Dynamics*

Engagement itself was also shaped by children's self-systems and by the support provided by their teachers. The clearest contributor to engagement was a sense of autonomy. Autonomy was a particularly strong predictor of changes in emotional engagement and disaffection—especially, as expected, of changes in boredom and frustration. Children who started the school year high in autonomy were likely to show improvements in their effort and enjoyment as the year progressed, whereas children low in autonomy (who felt externally or internally pressured) were likely to show increasing disaffection, both withdrawing their behavioral participation and feeling increasingly more bored and frustrated.

Competence made the strongest contributions to behavioral engagement and disaffection. Although not as strong a contributor to changes in emotional engagement overall, competence did seem to be a primary predictor of anxiety. Children with initially high levels of efficacy were likely to show improvements in their effort and exertion in class and to express moderate increases in their enjoyment and interest in learning activities over the school year. In contrast, children who started the school year doubting their capacities evinced increasing behavioral withdrawal from classwork accompanied by escalations in anxiety. Relatedness played a more central role in both kinds of engagement, but was not as strong a protective factor against disaffection. Children who began the year secure in their relationships with teachers increased in their effort and enjoyment, whereas children with less secure relationships with teachers were somewhat more likely to withdraw their efforts and to express boredom as the year progressed.

### *Role of Teacher Support*

The findings of this study suggest that teacher support also plays a central role in the motivational dynamics of engagement. If teacher reports of the support they provide are seen as markers of actual teacher support, then findings showed a pattern in which actual support is more important to behavioral engagement and disaffection (than to its emotional counterparts), whereas children's perceptions play a role in shaping changes in all facets of their participation in the classroom. Moreover, mediational analyses suggested that the contributions of teachers' support to changes in students' behavioral engagement are transmitted through their effects on children's perceptions of their interactions

with teachers. Students' perceptions of teacher support seemed to contribute to changes in engagement over the school year by shaping children's views of themselves as competent, autonomous, and related to teachers.

### *Self-System Model of Motivational Development*

The results of this study are largely congruent with the motivational model that suggests that teacher support, through its effects on students' perceptions of their interactions with teachers, shapes student self-systems over the school year, which in turn are strong predictors of all facets of their engagement. Engagement itself takes on its own dynamics, in which engagement and disaffection, through the reciprocal effects of behavior and emotion, tend to amplify themselves over time. These dynamics may explain the high interindividual stability within the motivational system, accompanied by slow declines that are portioned out differentially depending on initial levels of motivational resources. It should be noted that these connections do not differ as a function of gender or grade. The motivational processes that underlie the correlational results, although played out at different mean levels, seem to characterize all the gender and age groups examined in this study.

### *Implications for Conceptualizations of Engagement*

This study speaks directly to a set of issues raised in current reviews of the construct of engagement: how the components of engagement are similar and different from each other and how they work together over time (Fredricks et al., 2004; Jimerson et al., 2003). On one hand, the four indicators of engagement are similar in many ways: They are all relatively stable over the school year, at the same time that they are all worsening somewhat. They are all shaped both by teacher support and by students' self-perceptions, especially of autonomy, and the four indicators are all correlated with each other highly enough that they could reasonably be combined to form a single internally consistent bipolar construct.

On the other hand, each component has its own distinctive antecedents and its own role in the internal dynamics of engagement. The core construct, most prototypical of engagement, is behavioral participation in the classroom. In this sample, it had the highest mean level, the lowest cross-time stability, and the fastest drop across the school year. Behavioral engagement registered the biggest internal effects from emotional engagement and disaffection and from each of the differentiated disaffected emotions, especially boredom. It also registered the biggest effect from the SSPs, especially competence, and was the only indicator shaped by both teacher and student reports of teacher support. Hence, behavioral engagement seems to be a good summary indicator, diagnostic of the state of the entire motivational system. At the same time, however, it is not a strong contributor to changes in the other facets of engagement—it is not a big booster of subsequent enjoyment and interest, nor can it forestall emotional disaffection.

Compared with behavioral engagement, emotional engagement has a somewhat different profile: It is lower in mean level, a bit more stable, and loses less ground over the school year. However, it also seems to be a sensitive barometer of the whole motivational system, as emotional engagement was shaped over time by each SSP (with especially strong contributions from relatedness and autonomy) and also by students' perceptions of their interactions with teachers. Most

important, emotional engagement appears to be the active ingredient in sustaining motivation: It is the strongest contributor to the feedforward internal dynamics of engagement, bolstering behavioral engagement and staving off behavioral disaffection.

The two kinds of disaffection, which were both relatively low and interindividually stable, nevertheless seemed to feed on each other over time. Children who felt emotionally disaffected withdrew their effort over the school year, and as children stop participating, they became more emotionally alienated. Teacher support and the SSPs also played a role, especially in shaping behavioral disaffection. Analyses of the differentiated disaffected emotions suggest that children low in autonomy and relatedness are especially at risk for developing boredom; children low in perceived control, for escalating anxiety; and students low in autonomy, for increasing frustration.

### *Limitations of the Present Study*

Before discussing the implications of the findings further, the limitations of the current study must be taken into account. In terms of participants, this study focused on a group of middle- and working-class students who were largely Caucasian and were drawn from only two schools. Of course, it is noteworthy that modest declines in engagement were found even for this well-functioning group of students. However, it is important to be cautious about generalizing these results to subgroups who show the steepest declines in motivation. Even though many of the same findings have been documented in African American and low-income groups (Connell et al., 1994, 1995; Gutman & Midgley, 2000), little is known about the internal dynamics of engagement for these (or any other) children.

In terms of measures, the study relied heavily on student self-reports. Of course, students may be the only source for information about their SSPs, but it would have been helpful to include observational assessments of engagement and of interactions with teachers. In terms of design, the use of two points of measurement was a decided improvement over a one-time assessment. Nevertheless, time points at the beginning and end of the school year have no particular correspondence to the kind of episodic time during which these motivational cycles are hypothesized to unfold. It is more likely, for example, that the effects of student-teacher interactions on children's subsequent engagement play out over a period of weeks or months. A design that incorporates more frequent time intervals would be better suited to capture these dynamics (e.g., Schmitz & Skinner, 1993).

### *Implications for Theoretical Development and Future Research*

This study contributes to our growing understanding of the indicators and facilitators of engagement. The distinctions proposed between behavioral and emotional engagement and disaffection allowed for the study of how these components shape each other over time and uncovered enough differences in their operation to suggest that in future studies researchers must carefully consider whether they can be meaningfully combined. At the same time, these markers of classroom participation could themselves be distinguished from the self-systems and qualities of student-teacher interactions that have sometimes been included under the

broad conceptual sweep of "engagement" (Jimerson et al., 2003). Even if social contexts and self-perceptions are relevant and important (an assertion supported by this study), they should be unpacked from engagement itself if research is to investigate how these personal and social factors have an impact on the quality of students' participation in learning activities over time.

This study also suggests that future empirical efforts can build on the SSMMD by incorporating additional factors drawn from reviews of motivation and engagement (e.g., Wigfield et al., 2006). Other facets of engagement, especially cognitive forms, can be considered in relation to behavioral and emotional features, along with more disruptive forms of disaffection (Fredricks et al., 2004). Moreover, the general motivational dynamics are also likely to include additional components, for example, other facets of teachers' actions (such as competence feedback and their own enthusiasm) and the nature of the learning tasks students are required to undertake (especially the extent to which they are interesting, fun, and relevant). Other self-perceptions (e.g., goal orientations or values) can be incorporated as predictors of engagement and perhaps as alternative pathways through which teachers shape student motivation (Brophy, 2004; Stipek, 2002).

Perhaps most important, future studies can incorporate the assessment of important long-term motivational outcomes, such as identification with and commitment to school (Deci & Ryan, 1985; Finn, 1989, 1993), the internalization of the values of achievement and learning (Brophy, 1999; Eccles & Wigfield, 2002), and the development of the capacities and motivation for self-regulated learning (Ryan & Connell, 1989; Schunk & Zimmerman, 1994) or coping with academic difficulties and challenges (Skinner & Wellborn, 1994, 1997). These are the enduring motivational resources to which students' active enthusiastic participation likely contributes during late elementary school and that may act as protective buffers as students go through the normatively challenging transitions to middle and high school.

In sum, the general direction of this research appears promising as a source of insights about the dynamics of student engagement. The study suggests, for example, the centrality of children's interest and emotion in initiating and sustaining their participation in learning activities (e.g., Pekrun et al., 2002; Schutz & DeCuir, 2002) and highlights the burden that an emotion as commonplace as boredom can put on children's effortful involvement in academic tasks. Our results underscore the importance of student autonomy to engagement (Deci et al., 1985) as well as pointing out that its low mean level suggests that this need is not well met, even in this generally well-functioning group. At the same time, all of the self-systems we considered play a role—feelings of competence are needed to bolster exertion and persistence, and relatedness and autonomy are needed to spark the interest and enjoyment that sustains effort over time. Taken together, our findings suggest that the behaviors and emotions students present in class may provide teachers with a window on the inner workings of children's motivational resources and vulnerabilities (Furrer, Kelly, & Skinner, 2003). Patterns of engagement and disaffection may be diagnostic of the state of students' feelings of relatedness, competence, and autonomy, and if they are faltering, teachers may be able to figure out the kinds of motivational supports that could bolster them. Such compensatory teacher reactions may suggest one avenue for helping diminish or perhaps even reverse self-amplifying cycles of disaffection. Future studies focusing on these

and other questions of motivational dynamics may further elucidate the role of engagement in the long-term development of student academic resilience and success.

## Appendix

### Engagement Versus Disaffection With Learning: Student-Report

#### Behavioral Engagement

1. I try hard to do well in school.
2. In class, I work as hard as I can.
3. When I'm in class, I participate in class discussions.
4. I pay attention in class.
5. When I'm in class, I listen very carefully.

#### Emotional Engagement

1. When I'm in class, I feel good.
2. When we work on something in class, I feel interested.
3. Class is fun.
4. I enjoy learning new things in class.
5. When we work on something in class, I get involved.

#### Behavioral Disaffection

1. When I'm in class, I just act like I'm working. (–)
2. I don't try very hard at school. (–)
3. In class, I do just enough to get by. (–)
4. When I'm in class, I think about other things. (–)
5. When I'm in class, my mind wanders. (–)

#### Emotional Disaffection

1. a. When we work on something in class, I feel bored. (–)
- b. When I'm doing work in class, I feel bored. (–)

- c. When my teacher first explains new material, I feel bored. (–)
2. a. When I'm in class, I feel worried. (–)
- b. When we start something new in class, I feel nervous. (–)
- c. When I get stuck on a problem, I feel worried. (–)
3. When we work on something in class, I feel discouraged. (–)
4. Class is not all that fun for me. (–)
5. a. When I'm in class, I feel bad. (–)
- b. When I'm working on my classwork, I feel mad. (–)
- c. When I get stuck on a problem, it really bothers me. (–)
- d. When I can't answer a question, I feel frustrated. (–)

Indiana University–Purdue University at Indianapolis

This study examined the early interests of 109 children and their subsequent information contributions and pursuits in kindergarten. Four groups of children with similar interests were identified on the basis of the children's profiles of activities in the home, tracked bimonthly for over a year. Activity patterns reflected conceptual, social, procedural, or creative interests. The role of early interests in understanding academic engagement was investigated, with gender, cognitive skill, and temperament statistically controlled. Observational data from throughout the school year revealed differences in the types of information that children contributed to discussions and pursued in class related to children's early interests. Findings enrich understanding of young children's academic behaviors and extend theoretical models of academic self-instruction behaviors such as information exchanges and pursuits in classrooms.

**Keywords:** early childhood, personal interest, academic participation, information pursuits

Academically successful children institute an anthology of skills supportive of learning. Included among this repertoire of behaviors are self-initiated interactions with and quests for information (Zimmerman, 1989). For example, a good student actively contributes to scholarly discussions in the classroom and independently pursues information about academic topics, tasks, strategies, or performances, among other participation options. These interactions are a forum for students to access, elaborate, organize, integrate, or verify information and enhance understanding (Butler & Winne, 1995; Woloshyn, Pressley, & Schneider, 1992). The ability or willingness to adapt to the cognitive behavioral expectations of school has long-term as well as immediate effects on learning (Krapp & Fink, 1992). Consequently, it is important to understand the factors that may influence young children's academic uses and pursuits of information in the classroom.

Alexander, Department of Educational Psychology, Indiana University at Bloomington, Bloomington, Indiana; Kathy E. Johnson, Department of Psychology, Indiana University–Purdue University at Indianapolis, Indianapolis, Indiana.

This research was supported by National Science Foundation Grant BCS-9907865 to Joyce M. Alexander and Kathy E. Johnson and by a Proffitt research endowment grant from the School of Education at Indiana University. Thank you to Fabiola Reis-Henrie, Mary E. Leibham, Che-yu Kuo, Khidhir Zakaria, Christy Kendrick, and other research assistants at IUPUI and IU for their assistance on this project. We are very grateful to the children and parents who have graciously supported this research through their participation. We also thank the principals and teachers who welcomed us into their classrooms.

Children's personalities, cognitive abilities, and motivational dispositions have all been linked to their academic behaviors (Bjorklund & Schneider, 1996), and interest has been credited as the bridge linking cognition, motivation, and academic outcomes (Hidi & Harackiewicz, 2000; Pekrun, Goetz, Titz, & Perry, 2002). Although numerous studies have investigated the ways in which psychological state variables related to learning such as focus, effort, and persistence are affected by individual interest, the impact of interest on young students' means of academic participation in school—such as self-initiated information contributions and pursuits—has been relatively unexamined.

Children as young as 3 years already express intense interests in particular forms of activity (Renninger, 1989). Interest occurs when a certain object or event triggers a curiosity response or sense of enjoyment (Fink, 1994). Some interest theorists have proclaimed that it is best defined by the content of activity rather than the object of activity because even if interest may be piqued by particular objects, different materials elicit and support different types of experiences and interactions or action potentials (Renninger, 1984). In turn, interest influences not only the way a child engages in a given activity but also the child's representation of interaction possibilities (Renninger, 1990). Consequently, early interest-driven activity types may render certain transactions more familiar or some forms of information more valuable, and future interactions may be informed by early kinds of engagement (Renninger, 1990, 2000).

The study of interest from an action-potential perspective has received relatively little attention in empirical research. To date, the type of interest most heavily investigated has been topic interest (Schiefele, 2001), and in queue, studies of interest outcomes have focused almost exclusively on its influence on children's efficiency or effectiveness in learning subject- or domain-relevant information (Hidi & Anderson, 1992; Hidi, Berndorff, &

Ainley, 2002; Schiefele, 1990, 2001) or intensity and duration of involvement, dispositions, and motivation to learn in areas of interest (Hidi, 1990; Hidi & McLaren, 1991; Renninger & Leckrone, 1991; Schiefele, 2001). Studies of preschoolers have noted their use of interest objects as adaptive tools or security anchors and use of interest topics to initiate social contact with other children as they transition from home to school (Baum, Renzulli, & Hebert 1995; Krapp & Fink, 1992). However, the influence of interest may transcend content domains and exert more pervasive influence on children's participation patterns across settings. Early interests may direct subsequent participation strategy selection and use. Previous research with singular interest type foci has generated little information about how various interests may prepare children differently for interactions with academic information.

The present study examined children's interest-based activities in the home during early childhood and their subsequent contributions to academic discussions and quests for information in kindergarten. Temperament and cognitive characteristics of the child that could compete to explain differences in these academic behaviors were controlled. Consequently, this study offers an examination of the unique role of various early childhood interests for understanding differences in young children's uses and solicitations of information across domains and learning contexts in school.

### Children's Interests Expressed Through Play

Renninger and Wozniak (1985) suggested that children's interests can be identified by examining their time spent and level of engagement in particular activities relative to others. The activities in which young children consistently involve themselves are believed to reflect general orientations or socialized preferences for particular features of engagement (Krapp, Hidi, & Renninger, 1992; Renninger, 1989). Recent research has supported the notion that young children's pattern of activities may be indicative of some underlying comprehensive interest (Renninger, 1989) and shows that children themselves categorize their play on the basis of features or attributes of particular activities (Holmes, 1991). In fact, consistency has been noted in the action types of young children even in engagements with different objects (Renninger & Leckrone, 1991; Saracho, 1995). Therefore, young children's profiles of activity may be a better indicator of their interests than time spent within any single area of play.

Previous research has identified three attributes of activity that characterize interests in early childhood: material versus social focus, property or process referent, and reproductive versus transformative potential (Renninger, 1984). Some children are more focused on material-based activities best described as property or concept oriented (Renninger, 1989). During concept-oriented activity, the child focuses on object domain-specific or topical information exploration (Fink, 1994). Other children are focused more on particular practices or actions with objects (Renninger, 1989), referred to as process-oriented activity. These activities vary in how prescribed the schemas or scripts are that guide them (Johnson, Christie, & Yawkey, 1987; Pulaski, 1970; Renninger, 1984). Some materials have prescribed uses and functions, and the schemas or scripts that guide such activity are limited. Other materials are relatively free from intrinsic limits or structure, and thus, schema or script variability and transformative potential are

high. Therefore, process-oriented activity may be either highly structured (*procedural*), or open ended (*creative*). In contrast to children with these material-based interest types, some children are focused more on activities best described as socially oriented (Jennings, 1975; Krapp & Fink, 1992; Renninger, 1984). During socially oriented activity, the child is focused on enactment of social roles, routines, or processes.

Topical interests have been most heavily studied (Hidi et al., 2002; Schiefele, 1990, 2001); socially situated interests also have received attention in recent research (Sansone & Smith, 2000). These categories of interest as well as procedural and creative interests have been utilized in previous studies of vocational interest (Gati, 1991; Tracey, 1997). Less frequently, these categories have been used to describe differences in young children's personal interest types (Renninger, 1990), and, to date, this research has primarily examined intraindividual differences in children's play preferences. Presuming that individuals do have activity attribute penchants—material or social focused, property or process based, and structured or transformative preferences—children with common interests likely exhibit systematic similarities in the types of activities in which they spend their play time. This study examined children's profiles of play behaviors in the home to investigate the effects of differences in children's early childhood play interests and their subsequent academic involvement behaviors (contributions to discussion and pursuits of information) in school.

### Early Interests and Children's Academic Behaviors

Most studies of student learning approaches have been guided by views of academic involvement as a set of cognitive skills or a self-system trait (Vermunt, 1996, 1998). Students' levels and forms of participation in school have been correlated with—though distinctive from—general measures of cognitive skill (Zimmerman & Bandura, 1994; Zimmerman & Martinez-Pons, 1986). Personality characteristics have been associated with students' willingness to make use of opportunities to engage and sources of information in school (Birch & Ladd, 1998). In addition, research has shown that boys tend to control classroom conversations more than girls in the early elementary school years (Brophy, 1985; Jovanovic & King, 1998). Although the presence or absence of interest has been associated with children's level of engagement in school tasks (Schiefele, 2001), differences in children's personal interests have not been linked to their use of particular involvement strategies in classrooms. However, different interests lead to experiences that support different types of interacting and thinking (Sigel, 1993) and impact what and how a child learns (Baum et al., 1995; Renninger, 1990, 1992; Sansone, Weir, Harpster, & Morgan, 1992) by influencing the types of information that the individual attends to, deeply processes, and encodes (Hidi, 1990; Renninger, 1990; Renninger & Wozniak, 1985) as well as the individual's perceptions of values and expectations for behavior (Tobias, 1994). In these ways, interest serves as a mental and affective resource and leads to an enriched knowledge base and increased motivation to engage in particular ways (Ericsson & Smith, 1991; Hidi, 1990) that may have implications for children's involvement strategy selection in new events and settings.

Contemporary theories of interest distinguish between *situational interests*, which are triggered by external stimuli, and *individualized interests*, which are characterized by a relatively enduring predisposition to interact within a target domain (Krapp, 2002; Renninger & Hidi, 2002). However, theorists also assert that situational factors can both "catch" interest initially and "hold" it over time (Krapp, 2002) and that even individual interests are socially constructed and therefore are situational to some degree (Pressick-Kilborn & Walker, 2002). Whether intrinsically or extrinsically piqued, early interest-based activities maintained over time may exert some influence on subsequent interactions (Krapp, 2002). Therefore, differences in children's interest-based activities in early childhood may be related to the differences observed in children's contributions to academic discussions and information pursuits in kindergarten classrooms.

### *Contributions to Academic Discussions*

One's prior knowledge has a strong influence on cognitive engagement and forms of engagement with tasks (Winne, 1995). A well-developed knowledge base allows children to contribute to academic discussions in the classroom by equipping them with the tools with which they can work (Woloshyn et al., 1992). However, self-regulated academic behaviors, such as active participation, are contingent on motivational as well as cognitive factors (Zimmerman, 1986). Even young children with limited knowledge may participate actively if interested or motivated to do so. Specifically, children's sense of competence and control has been related to their level of engagement in classroom activities (Mischel & Shoda, 1995; Schunk, 1996). In addition, children have been found to be more involved in academic tasks when there is a perceived need or reason to exert effort, such as recognition of the value of learning or the desire to reap educational benefits (Sansone, Wiebe, & Morgan, 1999). Early interests that are better matched to the activities in school may relate to increased participation in classroom discussions, making interactions with information familiar and appreciable and more likely to be judged by children as within their competencies. However, during select interest-driven activities, children access, interpret, and construct understanding of information within a variety of categories, and certain types of activities that differ in focus (material or social), referent (property or process), and transformative potential may direct attention to particular kinds of information. As a result, even if children do not differ in how frequently they participate in classroom discussions, depending on their early interest orientations, they still may vary in the specific types of information they contribute to (or elicit from) discussions, such as task- or topic-relevant information, process or strategy information, or performance or personally relevant information.

### *Pursuits of Information*

Although children must attend to teacher instruction in order to learn, children also benefit from self-initiated pursuits of information through asking questions or soliciting assistance (Newman & Goldin, 1990; Ryan & Pintrich, 1997; van der Meij, 1990). The information that learners generate for themselves may enhance or update knowledge, introduce or inform procedures and strategies, or provide feedback related to performance expectations and suc-

cess (Resnick, 1987; Schneider & Pressley, 1997; Tobias, 1994). Factors that are related to whether children pursue information include their prior forms of knowledge (van der Meij, 1990) or achievement (Newman & Goldin, 1990), perceptions of their cognitive and social competence (Newman, 1990; Ryan & Pintrich, 1997), goals for learning (Butler, 1998; Newman, 1990; Ryan & Pintrich, 1997), and beliefs in the benefits of asking for help (Newman, 1990; Ryan & Pintrich, 1997). Experience within certain activities with either a material or social focus and property or process referent may render some forms of information more customary or familiar and provide encounters that make salient the relevance or usefulness of certain types of information. It seems plausible then to hypothesize that children's early interest-based activities in the home may influence the types of information they pursue in school, such as factual, task-process, or normative information.

### The Present Study

The present study rested on several assumptions: (a) interests affect what children pay attention to and encode, as well as how they allocate effort during activities aligned with the interest; (b) young children cultivate interests through their activities in the preschool years; and (c) different interests are associated with specific opportunities to develop specialized knowledge or specific schemas for engaging with the world. Subsequently, young children's patterns of involvement and interactions with particular forms of information in school may differ as a function of their interest histories. This study investigates these assumptions longitudinally, examining children's early childhood interest-based activities in the home and later variations in their contributions to academic discussions and pursuits of information in kindergarten. Given that variations in cognitive aptitude, temperament, and gender could mask the relations between children's interests and academic behaviors, we statistically controlled these variables in order to examine the unique contribution of children's interests to their patterns of participation and information pursuits in the classroom.

### Method

#### *Participants*

One hundred nine children (58 boys and 51 girls) who would enter kindergarten the next school year were recruited from a larger sample participating in a longitudinal study of early interest development. Children were between the ages of 4 years, 0 months and 4 years, 6 months at the onset of the study ( $M = 4$  years, 2 months) and between the ages of 4 years, 11 months and 6 years, 0 months at the time of entrance to kindergarten ( $M = 5$  years, 6 months). Children were recruited from two Midwest cities and neighboring communities.

The majority of children were White (88% White, 3% African American, 4% Asian American, 1% Latino, and 5% biracial) and from middle- to upper-middle-class families. The average number of years of parents' education was 16.03 ( $SD = 1.76$ ) for mothers and 16.51 ( $SD = 2.40$ ) for fathers. On average, the families had three children. Annual family income ranged from less than \$15,000 to more than \$100,000, with a mean of approximately

\$55,000 ( $SD = \sim \$35,000$ ). Children in the sample on average had spent approximately 18 hr ( $SD = 14.71$ , range = 0–52) per week in day care 1 year before school entry.

### Procedure

Data on children's personal characteristics and home activities collected at intake and throughout the 12 months prior to school entry were used for this study. During an initial laboratory visit, a battery of tests was administered to assess the child's receptive language skills, cognitive efficiency, and short-term memory. During this initial laboratory visit, parents provided basic child and family demographic background information. Parents also reported their child's activities in the home. Two months after the baseline assessment and continuing for 1 year, bimonthly interviews with parents were conducted to regularly update information about the child's activities. During a second laboratory visit at the beginning of the second year of the study (generally conducted 1–5 months before kindergarten began), the parents completed questionnaires about their child's temperament as well as their child's activities in the home.

Children were observed in their kindergarten classrooms so that aspects of academic engagement could be evaluated. Four doctoral students in educational psychology (blind to home activity data and to specific hypotheses) were trained during a 1-month period to use an observational coding system to assess the targeted academic behaviors. After interrater reliability of 90% was reached on practice tapes, observations in the classroom began. To monitor coder consistency, we conducted frequent reliability checks using a second coder throughout the study. Each research assistant observed and coded behaviors for approximately one quarter of the sample. All data for a particular child were collected by the same research assistant.

Classroom observations began in the first month of school and were complete by the end of April. The observer was seated in the classroom, close enough to view the child's work and listen to verbalizations. Throughout 5-min observation intervals, the observer tallied each occurrence of target academic behaviors. An audio cassette player with headset and an audiotaped cue were used to signal completion of the 5-min observation interval. At the conclusion of the 5-min observation interval, the observer counted tallies and recorded total frequencies for each of the academic behavior categories. Eighteen 5-min intervals of data for each child were collected during academic work in kindergarten: six during independent work, six during small-group work, and six during teacher-directed instruction, for a total of 90 min (30 min during independent work, 30 min during small-group work, and 30 min during teacher-directed activities). The observer began 5-min intervals of data collection only when academic activities occurred in an appropriate learning context. No more than six 5-min intervals of data were collected for each child during a single classroom visit. Consequently, for each child, data were collected during at least three class visits at intervals approximately equally spaced throughout the school year.

### Measures

**Child's temperament.** Mothers or fathers completed scales from the Child Behavior Questionnaire (Goldsmith & Rothbart,

1991), a widely used measure of child temperament. Six scales were used: inhibitory–control, activity level, attention, approach–anticipation, shyness, and intensity of emotion. Parents rated 58 items (8 from the attention scale and 10 items from each of the other five scales) on a 7-point Likert scale (1 = *low*, 7 = *high*). To create scores for each of the scales, we reverse coded and averaged scale items when necessary. For each of the scales, a high score indicates a high level of the temperament characteristic assessed. We calculated composite control and emotional responsiveness scores used as covariates in the principal analyses of the study by reverse coding when necessary and averaging the appropriate scales. The inhibitory–control or restraint, attention, and activity level (reversed) scores were used to create the control composite, a measure of the child's general self-control abilities ( $\alpha = .74$ ). Approach–anticipation, shyness (reverse coded), and intensity of emotion scores were used to create the emotional responsiveness composite, a measure of the child's receptiveness to the environment and extroversion ( $\alpha = .71$ ).

**Cognitive ability.** The child's cognitive ability was assessed with a battery of tests to measure three principal areas: language, analytic skill, and working memory. Language skills (receptive vocabulary) were assessed using the Peabody Picture Vocabulary Test (Dunn & Dunn, 1997). Analytic skill was assessed using accuracy scores from the Kansas Reflection–Impulsivity Scale for Preschoolers (KRISP; Wright, 1971). The KRISP was designed to assess the extent to which a child selectively attends to perceptual details and is systematic in the visual processing of pictures. Verbal working memory was assessed using the Working Memory–Sentences Test (Siegel & Ryan, 1989). We calculated a composite cognitive skill score for use as a covariate in the principal analyses by standardizing and averaging the child's scores on each of the three cognitive measures ( $\alpha = .69$ ). Higher or lower composite scores provide a general estimate of the cognitive resources available to the child (high scores indicate high cognitive resources).

**Children's interest-based activities in the home.** A bimonthly parent report was used to gather information about the child's activities in the home. We coded parent responses to the following four questions: (a) "What does your child prefer to do during his/her free play time?" (b) "What kinds of toys or objects (bought in stores as well as found in nature) does your child like to play with the most?" (c) "Are there any special pretend themes that seem to reoccur in your child's play?" and (d) "If your child had 1 hr to play anything s/he wanted, what do you think s/he would prefer?" There were no restrictions on number of activities parents could mention.

Information from parents' open-ended responses to questions concerning their child's activities across the year was used to create a profile of scores for each child. First, each child activity reported by the parent was categorized into one of eight major activity types derived from previous research on young children's play (Bergen, 1988; Saracho, 1995; Smilansky, 1968): topic-centered exploration, construction or mechanical activity, games with rules, physical activity and/or sports, literacy, art and/or music, fantasy, and sociodramatic activity (see Appendix). We calculated the percentage of activities within each of the types by dividing the number of reported activities aligned with that type by the total number of reported activities for the year. Final activity profile scores represent the percentage (relative frequency) of

reported activities in each type during the year. To assess inter-coder agreement for each activity type, two investigators double-coded 25% of the reported activities independently. A version of Cohen's kappa appropriate for frequency data (Bartko & Carpenter, 1976; Berry & Mielke, 1988) was calculated to evaluate interrater agreement for each activity type score in the profile. Kappas ranged from .83 to 1.00.

There was considerable variability in the play experiences of individual children. On average, a young child participated in about 16 different activities as part of routine play in the home across the year ( $M = 15.65$ ,  $SD = 4.44$ , range = 9–27). The frequencies of activities in this sample were similar to those reported from other large studies of 4- to 6-year-olds' play interests (Macari, Simock & DeLoache, 2003; Simcock, Macari, & DeLoache, 2002). Although the children engaged in a wide array of activities in their homes, their play tended to be narrowly distributed across the major domains. About one third of the children were engaged in activities distributed across two play domains, about one third were engaged in activities across three play areas, and one third of the children were engaged in activities across four domains. In line with characteristics of play behavior (property vs. process referent, material vs. social focus, structure vs. transformative potential) described by Renninger (1984, 1989) in previous research, patterns in the children's profiles were suggestive of underlying interests in particular forms and features of activity, seemingly indicators of conceptual, procedural, creative, or socially oriented interests. Children were assigned to one of four interest groups on the basis of evaluation of the defining characteristics of the activity types and combination of types prominent in their personal activity profiles (Table 1).<sup>1</sup>

Activity with a property referent and transformative potential distinguished the play of some children. These children, assigned to the *conceptual* interest group, spent the largest proportion of their activity in object or topic-centered explorations (63%). Their activities were characterized by interactions with materials with a focus on topical concepts (e.g., dinosaurs, astronomy) and the acquisition of domain-relevant information. Process-based systematic or programmatic activity with a material focus distinguished the play of other children. These children, assigned to the *procedural* interest group, spent large portions of their activity in construction or mechanical activities (23%), games with rules (16%), and sports (19%). These activities were characterized by interactions in various processes with materials that had inherent structure or prescribed uses, such as blocks, puzzles, Legos, and erector sets, or predetermined goals and routines, such as board games, card games, and sports. Activity with a process referent, material focus, and transformative potential distinguished the play of another group of children. These children, assigned to the *creative* interest group, spent large portions of their activity in music or art (40%), fantasy (17%), and literacy (11%) activities: Their activities involved interaction in various processes with flexible materials that could be used innovatively (i.e., paints, crayons, clay, glue, scissors, paper and pencil, other craft objects, and musical instruments) or contexts in which the child could enter imaginary worlds (i.e., books, other media, fantasy play). Activity with inherent structure and an interpersonal focus distinguished the play of a final group of children. Children assigned to the *socially oriented* interest group spent the largest proportion of their activity in sociodramatic activities (58%). Their activities involved interac-

<sup>a</sup>Types of play distinguishing the activity of each interest group from all other interest groups on the basis of the results of Scheffé complex comparisons.

tions with toys that served as props for various types of social reconstructive role play (i.e., relationships, social roles, occupational themes).

We conducted two sets of analyses in order to verify that relatively homogeneous groups could be differentiated from patterns in the children's profiles of activities across the eight play types. First, we performed complex contrasts using the Scheffé multiple comparison procedure to determine if inimitable domains of activity differentiated each group from all other interest groups (Table 1). The percentage of topic-centered activities reported was significantly higher for children in the conceptual group than for all the other children,  $t(105) = 11.75$ ,  $p < .001$ . The percentages of reported involvement with construction or mechanical activities, games with rules play, and sports were significantly higher for children in the procedural interest group than for the other children,  $t(105) = 4.71$ ,  $p < .001$ ;  $t(105) = 2.25$ ,  $p = .02$ ; and  $t(105) = 2.17$ ,  $p = .03$ , respectively. The percentages of music and

<sup>1</sup> The purpose of the original larger study from which participants for the current study were drawn was to investigate expertise in early childhood. As a consequence, the current study may include more children with conceptual interests than one might expect to see in the general population of preschool-aged children. One might expect the other three interest types to be fairly evenly distributed; however, previous research indicates that only about one third of preschool children develop conceptual interests (Johnson et al., 2004).

art activities, fantasy play, and literacy activities reported was significantly higher for children in the creative interest group than for all the other children,  $t(105) = 7.69, p < .001$ ;  $t(105) = 5.49, p < .001$ ; and  $t(105) = 2.59, p = .01$ , respectively. The percentage of dramatic activities reported was significantly higher for children in the socially oriented interest group than for all the other children,  $t(105) = 6.32, p < .001$ .

Next, a k-means cluster analysis of the eight activity types (requesting four groups) was performed. Group assignments generated in the cluster analysis provided support for group assignments made on the basis of qualitative analysis (92% agreement). For the cases in dispute ( $n = 9$ ), final group placements were made on the basis of qualitative analysis rather than the mathematical solution (Anderberg, 1973).<sup>2</sup> Given support for our hypothesis that children's patterns of activity reflect underlying comprehensive interests in particular types of activities, we were able to proceed in the investigation of the study's principal hypothesis: Children's early interests expressed through play may be related to differences in children's academic behaviors in school.

*Children's academic behaviors in kindergarten.* We assessed the children's academic contributions and pursuits in the kindergarten classroom using an observational coding system adapted from an instrument developed in previous studies of children's academic self-regulation in third-grade (Stright, Neitzel, Sears, & Hoke-Sinex, 2001) and in kindergarten (Neitzel & Stright, 2003). The original system captured information only about children's frequency of contributions to discussions and information pursuits. Refinements were made to facilitate more detailed assessments through specification of the types of information contributed and pursued in the classroom. Because the likelihood of classroom environmental effects cannot be ignored, observations of each child were divided equally in three academic contexts—teacher-directed, small-group work, and independent work—in an effort to control for these effects and ensure a representative sampling of all the children's behaviors.

Frequency counts of three types of information contributions to class discussions were made: providing elaborations or extensions, sharing suggestions or rationales, and generating connections or associations. Instances of the child sharing topic- or project-related facts or details were counted as elaborations—extensions. Instances of the child offering possible solutions, explanations or rationales, or suggestions for strategies to try were counted as suggestions—rationales. Instances of the child making ties between the topic of discussion and personal experiences or relating that topic to other issues were counted as connections—associations. We calculated final scores for each information contribution type by adding the frequency counts for each behavior from all observation periods.

We assessed the child's pursuits of information in the classroom using frequency counts of instances in which the child sought information in the classroom from the teacher, a peer, or other resources in the classroom. The child's pursuits of three information types were coded as additional information, task-process information, or normative information. Instances of the child seeking objective, factual information or requesting more details about a topic of study were counted as pursuits of additional information. Instances of the child seeking task or process (mastery) information, which includes strategies, rationales, and explanations of procedures or how and why things work, were counted as task-process information pursuits. Instances of the child seeking infor-

mation for the purpose of making social comparisons, evaluating performance in relation to peers, or determining relative standing ("Did I do it the way it's suppose to be?" "How did everyone else do it?" "Is mine as good as his?") were counted as normative information pursuits. We calculated final scores for each type of information pursuit by adding the frequency counts for each behavior from all observation periods.

Previous research has shown high correlations between parent instructional support behaviors in the home and observations of children's subsequent classroom involvement behaviors (Neitzel & Stright, 2003; Stright et al., 2001) and between observations and teacher ratings of these classroom behaviors (Stright & Neitzel, 2003). To assess intercoder agreement for the academic information contributions and pursuits in this study, Carin Neitzel observed jointly with each of four trained graduate research assistants and independently coded 25% of the classroom observations done by each of the research assistants. The observations with each research assistant were conducted at intervals equally spaced across the data collection period. For each academic information contribution and pursuit type, we calculated intercoder agreement using a variation of Cohen's kappa appropriate for frequency data (Scott & Hattfield, 1985). Cohen's kappas ranged from .82 to .95 for types of contributions to class discussions and .83 to .97 for types of information pursued.

## Results

First, preliminary analyses were conducted in order to provide descriptive information about the children and their interest-based activities as well as their academic behaviors and to check the assumptions associated with analyses of variance with covariates. In addition to the initial analyses reported here, the distributions of each variable in each of the four interest groups also were examined statistically and graphically. All assumptions of normality, homogeneity of variance, and linearity were upheld. Next, we conducted two split-plot factorial analyses of covariance (ANCOVAs) to examine differences among the interest groups in their academic behaviors.

### *Children's Personal Characteristics and Interests*

Frequencies, ranges, means, and standard deviations were calculated for each of the child characteristics variables; and analyses were conducted to assess gender, cognitive aptitude, and temperament differences across the four interest groups. There were statistically significant differences in interest group membership based on gender,  $\chi^2(3, N = 109) = 29.49, p < .001$ , Cramer's  $V = .52$  (see Table 2). Boys more often than girls had concept-oriented interests (proportions of .36 and .12, respectively) and procedural interests (proportions of .38 and .16, respectively); girls more often than boys had creative interests (proportions of .37 and .09, respectively) and socially oriented interests (proportions of .35 and .17, respectively).

<sup>2</sup> To ensure that this grouping decision did not alter the findings, we conducted all group comparison analyses using both grouping methods. There were not significant differences in the outcomes of these analyses, and no changes in the interpretations or conclusions drawn as a result of the grouping decision.

Table 2  
*Play Interest Group Membership by Gender*

Gender	Interest group			
	Conceptual ( <i>n</i> = 27)	Procedural ( <i>n</i> = 30)	Creative ( <i>n</i> = 24)	Social ( <i>n</i> = 28)
Boys	21	22	5	10
Girls	6	8	19	18

There also were statistically significant differences among the four interest groups in children's personal characteristics, Wilk's  $\lambda = .70$ ,  $F(9, 250) = 7.52$ ,  $p < .001$ , partial  $\eta^2 = .18$  (Table 3). Specifically, there were differences among the interest groups in cognitive skill,  $F(3, 105) = 7.21$ ,  $p < .001$ , partial  $\eta^2 = .17$ ; control,  $F(3, 105) = 5.04$ ,  $p = .003$ , partial  $\eta^2 = .13$ ; and emotional responsiveness,  $F(3, 105) = 3.82$ ,  $p = .01$ , partial  $\eta^2 = .10$ . Follow-up tests revealed that on average, the children in the concept-oriented interest group had higher cognitive skills than the children in the creative,  $t(49) = 3.11$ ,  $SE = 0.18$ ,  $p = .002$ , and procedural,  $t(55) = 2.35$ ,  $SE = 0.17$ ,  $p = .02$ , interest groups. Typically, children in the creative and procedural interest groups had higher levels of control than children in the socially oriented interest group,  $t(50) = 3.15$ ,  $SE = 0.17$ ,  $p = .002$ , and  $t(56) = 3.51$ ,  $SE = 0.16$ ,  $p = .001$ , respectively. On average, children in the concept-oriented and socially oriented interest groups were more emotionally responsive than children in the procedural interest group,  $t(55) = 2.76$ ,  $SE = 0.19$ ,  $p = .007$ , and  $t(56) = 2.36$ ,  $SE = .18$ ,  $p = .02$ , respectively. There were no systematic differences between boys and girls in cognitive skill or temperament characteristics.

#### *Children's Academic Behaviors in the Kindergarten Classroom*

Ranges, means, and standard deviations were calculated for each of the academic behaviors observed during the 90 min of

classroom observation (Table 4). In addition, we conducted bivariate correlations to examine the relations among children's different academic behaviors. Children who frequently pursued additional information in the classroom were likely to add elaborations—extensions during class discussions ( $r = .65$ ,  $p < .001$ ) and were less likely to make associations—connections during class discussions ( $r = -.30$ ,  $p = .002$ ) or to pursue normative information ( $r = -.24$ ,  $p = .01$ ). Children who frequently pursued task-process information in the classroom were likely to offer suggestions—rationales during class discussions ( $r = .49$ ,  $p < .001$ ) and to pursue normative information ( $r = .19$ ,  $p = .05$ ). Children who frequently made connections—associations were less likely to elaborate or extend class discussions ( $r = -.25$ ,  $p = .01$ ) but were more likely to offer suggestions—rationales during discussions ( $r = .24$ ,  $p = .01$ ) and to pursue normative information ( $r = .19$ ,  $p = .05$ ).

A series of multivariate analyses of variance (MANOVAs) were conducted to determine whether there were systematic differences between boys and girls in their frequency of academic behaviors in the classroom. In general, boys more often than girls contributed to class discussions, Wilk's  $\lambda = .83$ ,  $F(3, 105) = 7.17$ ,  $p < .001$ , partial  $\eta^2 = .17$ , and pursued information in class, Wilk's  $\lambda = .77$ ,  $F(3, 105) = 10.55$ ,  $p < .001$ , partial  $\eta^2 = .23$ . Specifically, follow-up analyses of variance (ANOVAs) on each behavior revealed that boys more often than girls provided elaborations—extensions,  $F(1, 107) = 15.77$ ,  $p < .001$ , partial  $\eta^2 = .13$ , and suggestions—rationales,  $F(1, 107) = 8.71$ ,  $p = .004$ , partial  $\eta^2 = .08$ . Girls did not differ from boys in their frequency of connections—associations made during class discussions. Boys more often than girls pursued additional information,  $F(1, 107) = 13.68$ ,  $p < .001$ , partial  $\eta^2 = .11$ , and task-process information,  $F(1, 107) = 8.96$ ,  $p = .003$ , partial  $\eta^2 = .08$ . Girls did not differ from boys in their normative information pursuits.

The relations among child characteristics and academic behaviors were examined through bivariate correlations. Children who had higher cognitive skills were likely to share more elaborations—extensions in class discussions ( $r = .26$ ,  $p = .01$ ) and pursue

Table 3  
*Means, Standard Deviations, and Ranges in Personal Characteristics of Children in Each Play Interest Group*

Personal characteristic	Interest group			
	Conceptual ( <i>n</i> = 27)	Procedural ( <i>n</i> = 30)	Creative ( <i>n</i> = 24)	Social ( <i>n</i> = 28)
Child cognitive skill

Range	3.82–5.08	3.36–5.48	3.76–6.48	3.11–5.41

*Note.* Means sharing a common subscript are not significantly different by the Dunn–Sidak multiple comparison test ( $p < .05$ ).

Table 4  
*Descriptive Statistics for Children's Academic Behaviors During 90 Min of Observation (N = 109)*

Child academic behaviors	<i>M</i>	<i>SD</i>	Range
Contribution to class discussions			
Elaboration-extension	3.82	3.20	0-13
Suggestion-rationale	5.06	3.73	0-14
Connection-association	4.47	3.27	0-12
Pursuit of information			
Additional information	2.10	1.98	0-9
Task-process information	3.63	2.77	0-13
Normative information	4.55	2.93	0-13

additional information at higher frequencies ( $r = .25, p = .01$ ). Children described as higher in control were more likely to offer suggestions-rationales during discussions ( $r = .23, p = .02$ ) and pursue task-process information in class ( $r = .19, p = .04$ ). Children described as higher in responsiveness were less likely to pursue task-process information ( $r = -.23, p = .02$ ); however, they were likely to pursue normative information more frequently ( $r = .19, p = .05$ ).

#### *Differences in Children's Academic Behaviors Related to Children's Interests*

We statistically controlled children's gender, cognitive skills, and temperament, characteristics that could compete to explain differences in children's academic behaviors by entering them as covariates in all analyses. Statistical removal of the variance in children's behaviors associated with their gender, cognitive skills, and temperament permitted an examination of the distinctive contribution of children's interests to understanding differences in their contributions to class discussions and information pursuits in kindergarten.<sup>3</sup>

**Contributions to discussions.** We conducted a split-plot factorial 4.3 analysis of covariance (ANCOVA) to examine children's participation in discussions. Children's interest type was the between-subjects factor (four levels), and children's type of contributions to class discussions was the within-subjects factor (three levels), with the effects of children's gender, cognitive skill, and temperament being controlled. However, gender was the only covariate with a significant unique effect on children's overall frequency of contributions to classroom discussions,  $F(1, 93) = 6.81, p = .01$ , partial  $\eta^2 = .07$ .

In the between-subjects analysis of variance, there were no differences among the interest groups in their overall frequency of participation in discussions in the classroom,  $F(3, 101) = 0.44, p = .73$ , partial  $\eta^2 = .01$ . In the within-subjects analysis, significant differences in frequency were found in the types of information that the children contributed to discussions in class,  $F(2, 100) = 4.96, p = .01$ , partial  $\eta^2 = .10$ . In general, the children contributed suggestions-rationales more often than elaborations-extensions. However, a significant interaction signaled differences in the types of information children contributed to discussions depending on their interests,  $F(6, 202) = 3.65, p = .002$ , partial  $\eta^2 = .10$  (see Figure 1).

To identify the differences in children's profiles of contributions to discussions, we conducted factorial profile (repeated measures)

analyses and post hoc comparisons for each group to examine differences in the types of contributions made within each interest group, controlling for the familywise error rate using Holm's sequential Bonferroni approach (Table 5; comparisons across each row). There were significant differences in the frequency of behaviors within the profiles of each interest group: conceptual,  $F(2, 52) = 5.76, p = .005$ , partial  $\eta^2 = .18$ ; procedural,  $F(2, 58) = 6.10, p = .004$ , partial  $\eta^2 = .17$ ; creative,  $F(2, 46) = 4.66, p = .01$ , partial  $\eta^2 = .17$ ; and socially oriented,  $F(2, 54) = 4.67, p = .01$ , partial  $\eta^2 = .15$ . Children with conceptual interests shared elaborations-extensions more often than they made connections-associations,  $t(26) = 2.93, SE = 0.96, p = .01$ . Children who had procedural interests shared suggestions-rationales more often than elaborations-extensions,  $t(29) = 3.36, SE = 0.91, p = .002$ , or connections-associations,  $t(29) = 2.36, SE = 0.87, p = .03$ . Children with creative interests made connections-associations and shared suggestions-rationales more often than elaborations-extensions,  $t(23) = 2.49, SE = 0.95, p = .02$ , and  $t(23) = 3.02, SE = 0.73, p = .01$ , respectively. Children with socially oriented interests made connections-associations more often than elaborations-extensions,  $t(27) = 2.55, SE = 0.83, p = .02$ .

In addition, a series of one-way ANCOVAs and Holm's sequential Bonferroni follow-up comparisons were conducted to assess differences among interest groups in the frequency of their three types of contributions to class discussions with the effects of children's gender, cognitive skill, and temperament controlled (Table 5; comparisons within each column). There were significant differences among groups in their elaborations-extensions,  $F(3, 101) = 3.98, p = .01$ , partial  $\eta^2 = .11$ ; suggestions-rationales,  $F(3, 101) = 2.95, p = .04$ , partial  $\eta^2 = .08$ ; and connections-associations,  $F(3, 101) = 2.61, p = .05$ ; partial  $\eta^2 = .07$ . Children with conceptual interests provided elaborations-extensions more than children whose interests were procedural,  $t(55) = 2.86, SE = 0.83, p = .01$ ; creative,  $t(49) = 2.37, SE = 0.98, p = .03$ ; or socially oriented,  $t(53) = 2.99, SE = 0.94, p = .01$ . Children who had procedural interests talked about suggestions-rationales in class discussions more often than children who had socially oriented interests,  $t(56) = 2.84, SE = 0.68, p = .01$ . Children who had creative or socially oriented interests made connections-associations more often than children who had conceptual interests,  $t(49) = 2.68, SE = 1.03, p = .03$ , and  $t(53) = 2.52, SE = 1.01, p = .03$ , respectively.

**Information pursuits.** To examine children's information pursuit behaviors, we conducted a split-plot factorial 4.3 ANCOVA. Again, children's interest type was the between-subjects factor (four levels) and the children's type of informational pursuits was the within-subjects factor (three levels), with the effects of children's gender, cognitive skill, and temperament controlled. However, gender was the only covariate with a significant unique relationship to children's overall frequency of information pursuits in the classroom,  $F(1, 93) = 3.88, p = .05$ , partial  $\eta^2 = .04$ .

In the between-subjects analysis of variance, there were no differences among the interest groups in their overall frequency of information pursuits in the kindergarten classroom,  $F(3, 101) =$

<sup>3</sup> It should be noted that the outcomes, interpretations, and conclusions drawn from initial analyses conducted without covariates included did not change with entry of the covariates.

Figure 1. Plot of interactions between children's interests and types of contributions made to academic discussion in the kindergarten classroom.

1.12,  $p = .34$ , partial  $\eta^2 = .03$ . In the within-subjects analysis, significant differences in frequency were found in the types of information that the children pursued in the classroom,  $F(2, 100) = 26.25$ ,  $p < .001$ , partial  $\eta^2 = .34$ . In general, the children pursued normative information more often than additional and task-process information and pursued task-process information more often than additional information. However, a significant interaction signaled differences in the types of information the

children pursued depending on their interests,  $F(6, 202) = 8.81$ ,  $p < .001$ , partial  $\eta^2 = .21$  (see Figure 2).

To identify the differences in the children's profiles of information pursuits and the frequency of the types of information pursued within each of the interest groups, we conducted factorial profile (repeated measures) analyses and post hoc comparisons, controlling for familywise error rate using Holm's sequential Bonferroni approach (Table 6; comparisons across each row). Children who had conceptual interests did not differ in the frequency of their pursuits of the various types of information,  $F(2, 52) = 0.95$ ,  $p = .39$ , partial  $\eta^2 = .04$ , but there were significant differences in the frequency of behaviors within the profiles of children whose interests were procedural,  $F(2, 58) = 19.38$ ,  $p < .001$ , partial  $\eta^2 = .40$ ; creative,  $F(2, 46) = 18.42$ ,  $p < .001$ , partial  $\eta^2 = .45$ ; and socially oriented,  $F(2, 54) = 35.75$ ,  $p < .001$ , partial  $\eta^2 = .57$ . Children who had procedural interests sought task-process information and normative information more often than additional information,  $t(29) = 5.71$ ,  $SE = 0.65$ ,  $p < .001$ , and  $t(29) = 5.10$ ,  $SE = 0.74$ ,  $p < .001$ , respectively. Children with creative interests

Table 5

Post Hoc Comparisons Examining Differences in the Frequency of Types of Contributions to Class Discussion Within Each Interest Group (Rows) and Between Interest Groups For Each Type of Contribution to Class Discussions (Columns)

Interest group	Frequency of contributions to class discussion		
	Elaborations or extensions	Suggestions or rationales	Connections or associations
Conceptual ( $n = 27$ )			
<i>M</i>	5.70 <sub>a,c</sub>	4.25 <sub>a,b,c,d</sub>	2.82 <sub>b,d</sub>
<i>SE</i>	0.64	0.75	0.73
Procedural ( $n = 30$ )			
<i>M</i>	3.33 <sub>b,d</sub>	6.13 <sub>a,c</sub>	4.22 <sub>b,c,d</sub>
<i>SE</i>	0.64	0.79	0.73
Creative ( $n = 24$ )			
<i>M</i>	3.38 <sub>b,d</sub>	5.67 <sub>a,c,d</sub>	5.59 <sub>a,c</sub>
<i>SE</i>	0.75	0.92	0.86
Socially oriented ( $n = 28$ )			
<i>M</i>	2.89 <sub>b,d</sub>	4.19 <sub>a,b,d</sub>	5.36 <sub>a,c</sub>
<i>SE</i>	0.68	0.83	0.77

Note. Frequency of contributions = estimated means after model covariates (child characteristics: gender, cognitive skill, control, and emotional responsiveness) were controlled. For each interest group, means sharing a common subscript are not significantly different by the Holm's sequential Bonferroni comparison procedure ( $p < .05$ ). Subscripts a and b denote comparisons across each row (within-group comparisons). Subscripts c and d denote comparisons within each column (between-group comparisons).

Table 6  
*Post Hoc Comparisons Examining Differences in the Frequency of Types of Information Pursuits Within Each Interest Group (Rows) and Between Interest Groups (Columns) for Each Type of Information Pursuit*

Interest group	Frequency of information pursuit		
	Additional information	Task-process information	Normative information
Conceptual ( <i>n</i> = 27)			
<i>M</i>	3.66 <sub>a,d</sub>	2.80 <sub>a,e,f</sub>	3.80 <sub>a,e</sub>
<i>SE</i>	0.36	0.56	0.61
Procedural ( <i>n</i> = 30)			
<i>M</i>	1.45 <sub>b,e</sub>	4.99 <sub>a,d</sub>	5.36 <sub>a,d</sub>
<i>SE</i>	0.36	0.56	0.61
Creative ( <i>n</i> = 24)			
<i>M</i>	1.62 <sub>c,e</sub>	4.67 <sub>a,d,e</sub>	2.89 <sub>b,e</sub>
<i>SE</i>	0.42	0.65	0.71
Socially oriented ( <i>n</i> = 28)			
<i>M</i>	1.72 <sub>b,e</sub>	2.08 <sub>b,f</sub>	5.82 <sub>a,d</sub>
<i>SE</i>	0.38	0.59	0.64

*Note.* Frequency of information pursuit = estimated means after model covariates (child characteristics: gender, cognitive skill, control, and emotional responsiveness) were controlled. For each interest group, means sharing a common subscript are not significantly different by the Holm's sequential Bonferroni comparison procedure ( $p < .05$ ). Subscripts a, b, and c denote comparisons across each row (within-group comparisons). Subscripts d, e, and f denote comparisons within each column (between-group comparisons).

sought more task-process information than normative,  $t(23) = 3.00$ ,  $SE = 0.40$ ,  $p = .01$ , or additional,  $t(23) = 6.32$ ,  $SE = 0.40$ ,  $p < .001$ , information and more normative than additional information,  $t(23) = 2.97$ ,  $SE = 0.44$ ,  $p = .01$ . Children who had socially oriented interests sought normative information more than task-process,  $t(27) = 6.80$ ,  $SE = 0.56$ ,  $p < .001$ , or additional,  $t(27) = 6.39$ ,  $SE = 0.69$ ,  $p < .001$ , information.

In addition, we conducted a series of ANCOVAs and follow-up comparisons using the Holm's sequential Bonferroni approach to assess differences among the interest groups in frequency of their pursuits of each information type with the effects of children's gender, cognitive skill, and temperament controlled (Table 6; comparisons within each column). There were significant differences among groups in their pursuits of additional information,  $F(3, 101) = 8.82$ ,  $p < .001$ , partial  $\eta^2 = .21$ ; task-process information,  $F(3, 101) = 5.92$ ,  $p = .001$ , partial  $\eta^2 = .15$ ; and normative information,  $F(3, 101) = 5.16$ ,  $p = .002$ , partial  $\eta^2 = .13$ . Children who had conceptual interests pursued additional information more often than children whose interests were procedural,  $t(55) = 4.70$ ,  $SE = 0.47$ ,  $p < .001$ ; creative,  $t(49) = 3.29$ ,  $SE = 0.62$ ,  $p = .001$ ; or socially oriented,  $t(53) = 3.46$ ,  $SE = 0.56$ ,  $p = .001$ . Children who had procedural interests sought task-process information more often than children with conceptual,  $t(55) = 3.04$ ,  $SE = 0.72$ ,  $p = .003$ , and socially oriented,  $t(56) = 3.23$ ,  $SE = 0.90$ ,  $p = .002$ , interests. Children who had creative interests also asked for task-process information more often than children with socially oriented interests,  $t(50) = 3.08$ ,  $SE = 0.84$ ,  $p = .003$ . Children with creative and conceptual interests sought normative information less often than children with procedural interests,  $t(52) = -2.68$ ,  $SE = 0.92$ ,  $p = .02$ , and  $t(55) = -2.05$ ,

$SE = 0.76$ ,  $p = .04$ , respectively, or socially oriented interests,  $t(50) = -3.26$ ,  $SE = 0.90$ ,  $p = .002$ , and  $t(49) = -2.14$ ,  $SE = 0.94$ ,  $p = .03$ , respectively.

## Discussion

This is the first known prospective investigation of the relations between the interest-related activities of a fairly large sample of preschoolers and their classroom behaviors at school entry. This study offers a detailed account of the complex relations between children's interest-based activities in the home during the early childhood years and subsequent forms of academic participation in kindergarten.

Children in four interest groups (conceptual, social, procedural, and creative) did not differ in their frequency of information contributions and pursuits in the kindergarten classroom. However, exploration of the trends both between and within interest groups revealed differences among the groups in the frequency of various types of information contributions and pursuits as well as unique profiles of academic participation behaviors within each group. There was remarkable consistency between the types of information that the children offered in discussions and pursued in the classroom and those that the children likely experienced or practiced through interest-based activity routines. Although we are cognizant of the fact that there are likely mediator variables we have not measured that could account for this consistency, it quite plausibly reflects a relationship between children's early engagement with particular types of information through interest-based activities in the home and later ways of interacting with information in school.

### *Children's Interests and Academic Information Contributions and Pursuits*

Children who had process-oriented interests (both procedural and creative) offered suggestions and provided rationales during class discussions and actively sought task-process information more frequently than did children with other interest orientations. The activities characteristic of process-oriented interests often involve trial and error, examination of interrelations among factors, and investigation of alternative approaches to problems. Therefore, these activities may support the acquisition of information about how tasks work and generation of general strategies, routines, or procedures for approaching tasks (Vandenberg, 1980, 1990). In these activities, the children may have learned to pay attention to specific aspects of tasks and problem-solving situations.

Children who had creative interests differed from children who had procedural interests in their information pursuits in ways consistent with the experiences they likely had in their early childhood activities. The children who had creative interests pursued normative information much less often than did children who had other interests and made connections and associations more often than the other children. Children with creative interests may be unconcerned with information for the purpose of social comparison because the activities that are characteristic of their interests usually permit exploration of possibilities without established standards for evaluation (Pulaski, 1970, 1973; Sutton-Smith, 1979). These children may be unaware of performance assessment

routines or the usefulness of information that can be gained, or they simply may derive their own benchmarks by which they measure their progress. Open-ended activities also are a forum for the generation of novel ideas (Clark, Griffing, & Johnson, 1989) and associations (Cole & Lavoie, 1985). The connections made by children in the creative interest group may be artifacts of a predilection for unique approaches or interpretations and, therefore, may represent cognitive elaborations (Klein & Kihlstrom, 1986; Symons & Johnson, 1997), or creative children may use connections as instruments to increase interest (Sansone et al., 1992; Wolters, 1999). We did not distinguish between connections and associations that were novel conceptualizations and those that were personal links between classroom topics of discussion and previous experiences or ways of understanding. In future research, measurements that allow teasing apart the particular function of young children's connections and associations could be beneficial.

Children who had socially oriented interests often made connections and associations during class discussions but offered suggestions and rationales as well. They most frequently pursued normative information. The activities of children with socially oriented interests involve the use of toys or props in the enactment of roles about life experiences focused on relationships or the roles or rules and structure of society (Jennings, 1975). These information-seeking behaviors may simply be a mirror of the children's socially oriented interests, or they may be a function of a lack of experience or practice with activities that support other forms of knowledge or interaction routines (Ericsson, Krampe, & Tesch-Romer, 1993). Future research that examines the metacognitive talk of children in class may assist researchers in isolating the most appropriate of these interpretations.

Children who had concept-oriented interests offered more facts or details to discussions, elaborating on and extending academic conversations, and made fewer connections and associations than most children. In contrast to children from other interest groups, they sought additional information about topics of study as often as other types of information. Children with concept-oriented interests typically engage in activities that involve interactions with materials, books, and other media, often with the goal of acquiring domain-specific information (Johnson, Alexander, Spencer, Leibham, & Neitzel, 2004). Consequently, these children may possess better-developed knowledge bases as well as more experience with the integration and organization of information (Chi & Koeske, 1983; Mervis, Pani, & Pani, 2003). In this way, the interest-relevant activities that are familiar and valued may be better matched to the information-dominated activities emphasized in classrooms (Super & Harkness, 1986) and may prepare the children for participation of this type in school.

### *Children's Academic Behaviors in Kindergarten*

In contrast to previous studies of academic participation behaviors that have focused on older children or adolescents (for a meta-analysis, see Winne & Perry, 2000), this study offers a rich analysis of the academic information exchanges and pursuits of young children in school. Although, the primary purpose of this study was to examine the differential effect of children's early interests on their subsequent forms of academic engagement, we would be remiss to ignore an opportunity to at least briefly examine this rare portrait of young children's general academic partici-

ipation patterns, a profile of behaviors touted in prior research as important to achievement in school (Normandeau & Guay, 1998).

In general, the young children in this study were actively involved in discussions and in the pursuit of information. An argument could be made that the academic behaviors observed might be specific to children from relatively well-educated families; however, similar results have been found in observational studies of kindergarteners from less-educated families (Neitzel & Stright, 2003). During academic discussions, these children shared suggestions and rationales most often, although they customarily made connections and associations as well. Elaborations or extensions were more rare. In information pursuits in the classroom, the children asked for normative information routinely, more than they asked for task-process information or additional information about topics.

Although involved, the children may not seem to have been particularly self-reliant. However, young learners who were not self-directed and motivated probably would not care about how they performed. Habitual pursuits of normative information may reflect young children's desire to understand the standards of operation and expectations for performance in the academic setting (Bandura, 1986) or to obtain information about themselves as learners (Ferne, 1989). Therefore, we do not consider these self-regulation deficiencies. Social comparisons allow young children to determine the appropriateness of their academic behaviors and appraise their performances (Butler & Winne, 1995; Ruble, 1987; Ruble & Flett, 1988). As a result, evaluations against normative standards also can promote self-efficacy (Schunk, 1987, 1996; Schunk & Hanson, 1989).

Similarly, connections and associations offered during class discussions may represent young children's attempts to locate their place within the academic arena or to establish personal relevance. Brophy (1999) has argued that for learning to occur, the material to be learned must be potentially meaningful. Personal references may be tactics used to establish links to new material (Masten & Coatsworth, 1998; Sansone & Smith, 2000; Spires & Donley, 1998). Children's connections and associations also may reflect strategic efforts to enhance learning through the integration of new information with existing knowledge (Symons & Johnson, 1997).

Often, solicitation of normative information and reliance on self-relevant ties have been described as precursors to or inhibitors of more independent or sophisticated forms of academic self-regulation (Schunk & Zimmerman, 1997; Wolters, 2004). These practices seem to conflict with the image of a mastery-oriented, motivated, and self-sufficient individual. However, these practices are probably valuable in situations that are unfamiliar or when understanding is fragile. Thus, these findings raise questions about whether different self-regulation strategies serve distinct functions at different times in development. This warrants attention in future research.

### *Implications for Parents and Teachers*

The information derived from this study has implications for both parents and teachers. Many parents worry about how best to support their young children as learners, and the kinds of experiences and structures they should put in place for optimal growth. At least in part, children's academic self-instruction behaviors seem to be cultivated and sustained in the course of routine

activity. Therefore, young children's early interests are not insignificant and may provide the fundamental context and processes for academic preparation. These findings suggest that opportunities to participate in a variety of experiences be made available to children in early childhood. Differences in children's early childhood experiences did not translate into differences in levels of engagement in school. All of the children in this study, regardless of their interest-based activities, participated equally in the classroom milieu.

In order to construct knowledge, learners must be actively engaged with information and activities available in classroom settings (McCaslin & Good, 1996). Participation is a critical tool for academic success (Schneider & Bjorklund, 1992). Reciprocally, information has a strong influence on cognitive engagement and forms of engagement with tasks (Winne, 1995). Teachers should be aware that although children with all types of experiences seem equally primed to participate in the classroom environment, differences in their histories of home activities mean that young children may come to school with different kinds of interaction preferences. Teachers need to be open to children's predictions for different types of information exchanges and queries and aware that each of the different types of participation may have important benefits for young learners.

These findings also serve as a reminder to teachers that young children rely on their feedback to learn about the values and behavioral expectations of school, and young children's initial presumptions about their competencies and capabilities are founded on information from external sources (Butler & Winne, 1995). Consequently, teachers must be careful about the expectations, values, goals, and attributions conveyed. Finally, teachers also should be cautious in the use of interest categories for understanding and evaluating the behaviors, needs, and potentials of young children. It certainly could be useful to capitalize on what is known about children's interest proclivities in the design of settings and instructional strategies to support young children as they transition to school, but it could be equally harmful if this information were used to narrowly define children. Although children may express preferences for particular kinds of experiences and interactions, children also engage in and enjoy a variety of activities. Recent research has shown that interests are susceptible to change, particularly as young children enter new social settings, encounter new opportunities, and expand their social networks (Wang, 2003).

### *Final Comments and Directions for Future Research*

Past research has linked childhood activities with cognitive development (Fisher, 1992), motivation (Christie & Johnsen, 1983), social competence (Creasey, 1998), and theory of mind (Lillard, 1998), which are all important tools for academic self-regulation. The fundamental assumption framing the present study was that early childhood activities serve as a context in which young children develop, express, and further cultivate interests. Another assumption guiding this study was that interest-based activities provide exposure to different experiences and opportunities to develop certain types of knowledge and interaction scripts or routines. As a result, children's early interests may lead to differences in their academic participation. The remarkable consistencies noted in children's interests and academic behaviors

sustain the plausibility of this explanation and compel further research.

We believe that individual interest could only be inferred from a child's persistence and consistency of engagement across various activity types; therefore, an effective investigation of our research hypotheses required a longitudinal tracking of children's home activities. Although converging observations of children's activities would have been ideal, this simply was not logistically feasible. Parents are apt to be better retrospective reporters of home activity histories than young children. It is true that parents could provide unreliable and biased accounts of their own children's activities. Research by Andre and Brown (1969) has suggested, however, that mothers perceive their children's interests relatively accurately. In addition, incomplete and erroneous reports only would have made it more difficult for systematic relationships between children's interests and academic engagement or differences among interests groups to be detected. The emergence of clear and theoretically consistent patterns of relations helps to reduce concerns associated with our reliance on parental report.

Additionally, in any attempt to examine children's academic behaviors, the likelihood of classroom setting effects cannot be ignored. We attempted to control for these effects by controlling for academic subject and instructional context. However, classrooms are complex contexts, and it would be difficult to identify—let alone to control for—all of the possible variations; therefore, it is quite likely that some error with the potential to mask the influence of early interests was introduced in the measurement of children's academic behaviors. However, meaningful patterns powerful enough to be noted over any "noise" in the data were uncovered. Still, future studies of these relations should include efforts to devise more sophisticated methods of controlling (or considering) important features of the classroom environment.

In this study, gender posed another methodological and conceptual challenge. Gender was related to children's interests as well as their academic behaviors, making it difficult to disentangle the influences of interest-based activity from those of gender. Consequently, despite our efforts to statistically control these effects, the question still may be raised about whether the differences observed in the present study in academic self-regulation behaviors are attributable to gender rather than to early interests. We maintain that patterns in the findings argue against gender as a primary explanation. If gender were the principal causal factor, the patterns in contributions to classroom discussions and pursuits would have been similar for the two interest groups predominately composed of boys (conceptual and procedural) and of girls (social and creative). This was not the case.

To the extent that children's personal characteristics such as gender, cognitive skill, and temperament were adequately controlled, this study provides a rare examination of the unique relations between children's interest-based activities in early childhood and academic self-instruction behaviors in school. Surprisingly few studies have controlled for individual difference factors that could confound such studies. However, more than a single score (or two) may be required to control for complex constructs such as cognitive skill and temperament. Sample size (although relatively large for a study of this type) imposed limits on the number of variables that could be included in the analyses. Replication with larger samples would enable the examination of more complex models. For example, a child's cognitive abilities, per-

sonal characteristics, and interests may work together to influence classroom behaviors. An alternative possibility is that a child's early childhood interests represent the juncture of personal and socialization factors and may be a more proximal source, mediator, or moderator of influence on behavior in new settings.

Interest in early childhood has been described as an artifact of social-contextual as well as interpersonal factors (Neitzel, Johnson, & Alexander, 2003). The material resources available, as well as procedures and structures instituted within the home, help shape children's expectancies, values, goals, and mental models for roles and action possibilities (Pintrich & Schrauben, 1992; Super & Harkness, 1986). Consequently, knowledge and interaction routines cultivated during early childhood activities may be fundamental to children's academic behaviors, or the same processes that support the emergence of particular interests in the home also may support the development of children's academic behaviors, or both may contribute uniquely. Additional research is needed to simultaneously examine the direct and indirect influences of important elements of the home environment and individual cognitive and personal resources of the child.

Further research also is needed to examine how long connections between early interests and academic behaviors endure. Findings in the present study suggest the influence of children's early interests appears relatively pervasive across the first year of school. However, as children spend increasingly more time in school, the many new and intriguing ideas and experiences encountered may exert greater influence. Thus, children are likely to move away from early predilections, making the influence of childhood interests less prominent over time. On the other hand, if early schemas for interactions are maintained, the influence asserted may persist. Investigation of these and other important questions will enhance theoretical models of academic self-regulation development in which the individual and social contexts each assume important roles.

## Appendix

## Interest Orientation Types; Toys or Materials; and Activities

Orientation/interest type	Toys or materials	Characteristic activities
Concept orientation—conceptual interest: Topic-centered exploration.	Interaction with toys or materials with a focus on object concepts and features. Characteristic topics: Dinosaurs, trains, insects, astronomy, geographic locations, ocean life, weather.	Seeking focal object/topical information (i.e., interactions with adults, books, media, or other information sources); questioning; organizing and managing information and object- or topic-relevant experiences.
Process orientation		
Procedural interest		
Construction or mechanical	Organizational toys designed for arrangement of parts: Puzzles, Cuisenaire rods, blocks, Legos, Tinker toys, peg boards, erector sets, models.	Examining interrelations of factors, one-to-one correspondence, and part-to-whole concepts; matching or grouping; producing; generating solutions; engaging in trial-and-error learning; investigating and evaluating alternate methods; practicing task process.
Games with rules	Board games, checkers, chess, tag, and hide and seek.	Practicing game-relevant skills, procedures/process information, strategies, and problem solving.
Physical or motor	Gross motor toys (e.g., swings, slides, bicycles, skates, and jump ropes) and sports equipment (e.g., bats, balls, and Frisbees).	Practicing relevant skills, procedures/process information, strategies, and problem solving.
Literacy (also may be creative, depending on activity focus)	Books, story books with tapes, reading and writing activities.	Focusing on learning the skill or process of reading.
Creative interest		
Art and music	Art supplies (e.g., paints, crayons, pencils and paper, markers, clay, play dough, scissors, glue, other craft materials); CDs or tapes; instruments; dance props; microphones.	Engaging in self-expression, creation, production, and generation of ideas or alternative methods; exploring material uses or transformations; processing information.
Fantasy	Materials used in imaginative, nonliteral ways; enactment of fictitious roles removed from everyday experiences (super heroes, fairy tales, cartoon characters).	Imagining; transforming materials and tasks; recognizing relations; making connections and associations; showing openness and flexibility; using imagery and symbolic representation.
Literacy (or may be procedural, depending on focus)	Books, story books with tapes, reading and writing activity.	Entering world of make-believe; expressing; practicing new roles.
Social orientation		
Dramatic play: Focus on relationships	Dolls and accessories, kitchen sets and other housekeeping props, dress-up clothes (may represent a variety of thematic roles).	Engaging in symbolic representation and verbal communication; enacting roles about life experiences; taking on adult roles/tasks, representing what is understood; practicing and testing understanding.
Dramatic play: Focus on social process	Miniature props: Cars, trains, bulldozers, and so on; buildings for community/occupational themes (houses, fire stations, airports, farm sets, mechanic garages).	Using props to enact roles and to imitate and recreate structures and procedures of society, exhibiting attention to social structure, roles, rules, and procedures.

# Supporting Students' Motivation, Engagement, and Learning During an Uninteresting Activity

Hyungshim Jang  
University of Wisconsin—Milwaukee

The present study examined the capacity of 2 different theoretical models of motivation to explain why an externally provided rationale often supports students' motivation, engagement, and learning during relatively uninteresting learning activities. One hundred thirty-six undergraduates (108 women, 28 men) worked on an uninteresting 20-min lesson after either receiving or not receiving a rationale. Participants who received the rationale showed greater identified regulation, interest-enhancing strategies, behavioral engagement, and conceptual learning. Structural equation modeling was used to test 3 alternative explanatory models to understand why the rationale produced these benefits—an identified regulation model based on self-determination theory, an interest regulation model based on interest-enhancing strategies research, and an additive model that integrated both models. The data fit all 3 models; however, only the model that included rationale-enhanced identified regulation uniquely fostered students' engagement and hence their learning. Findings highlight the role that externally provided rationales can play in helping students generate the autonomous motivation they need to engage constructively in and learn from uninteresting, but personally important, lessons.

**Keywords:** rationale, autonomous motivation, identified regulation, interest regulation, self-determination theory

As students make the transition from elementary to middle school and from middle school to high school, their workload becomes greater, academic work increases in difficulty, grading becomes more stringent, and instruction becomes less personalized (Eccles & Midgley, 1989). Not surprisingly, students' academic motivation steadily declines following this transition, as children's mostly intrinsically motivated orientation gives way to adolescents' mostly extrinsically motivated orientation (Harter, 1981, 1982). In a similar vein, students—and especially older students—report finding the learning activities they encounter in school to be lacking in direct or personal relevance to their lives as well as unexciting, unappealing, overly complex and difficult, and/or more time consuming than they prefer (Anderman & Maehr, 1994; Eccles & Midgley, 1990; Eccles & Wigfield, 1995; Goodlad, 1984; Haladyna & Thomas, 1979; Hidi & Harackiewicz, 2000; Wigfield & Eccles, 2000). When students fail to value what they are asked to learn in school, the degree of student motivation to engage in the target learning activity significantly decreases (Legault, Green-Demers, & Pelletier, 2006; Murdock, 1999; Wigfield & Eccles, 2000). This devaluing process predicts students' subsequent minimal effort, poor concentration, indifference, and general withdrawal from the activity (Legault et al., 2006; Ntoumanis, Pensgaard, Martin, & Pipe, 2004; Vallerand, Fortier, & Guay, 1997; Vallerand et al., 1993). Consequently, teachers often find themselves facing a difficult motivational problem when they attempt to motivate students during uninteresting (from the stu-

dent's perspective), but potentially important (from the teachers' perspective), academic activities.

## The Relation Between Values and Academic Engagement and Performance

A substantial body of research on values and academic behaviors suggests that when students value a learning activity in terms of high task value, utility value, interest value, attainment value, instrumental value, future goals, future consequences, future time perspective, and/or intrinsic goals, they become increasingly likely to actively engage in that topic, to persist in that topic over time, to achieve highly, to show relatively sophisticated self-regulation, and to understand what they are trying to learn (DeVolder & Lens, 1982; Husman & Lens, 1999; Miller & Brickman, 2004; Miller, Greene, Montalvo, Ravindran, & Nichols, 1996; Shell & Husman, 2001; Vansteenkiste, Simons, Lens, Soenens, & Matos, 2005; Wigfield & Eccles, 2000). All these studies support the general conclusion that students tend to invest more effort and achieve more when a lesson is perceived to have personal importance or relevance.

The particular importance of these findings to teachers is that when teachers try to find ways to promote students' motivation during relatively uninteresting (but potentially important) learning activities, they can successfully do so by promoting task value. One way teachers can help students value the uninteresting, but important, learning task is by providing a rationale that (a) identifies the lesson's otherwise hidden value, (b) helps students understand why the lesson is genuinely worth their effort, (c) communicates why the lesson can be expected to be useful to them, and/or (d) helps students see or discover the personal meaning within a lesson. When successful, this instructional strategy can

Correspondence concerning this article should be addressed to Hyungshim Jang, Department of Educational Psychology, University of Wisconsin—Milwaukee, 709 Enderis Hall, Milwaukee, WI 53201. E-mail: hjang@uwm.edu

help create an opportunity for students to perceive, accept, and personally endorse—hence internalize into the self-system—the value of the learning activity.

### Purpose of the Present Study

Individual students bring their own influential characteristics (e.g., ability beliefs, personal interest, values) into the classroom. However, characteristics in the learning environment also affect students' motivational states, such as their interest, valuing, and effortful engagement. Focusing on these social-contextual conditions, the present study examined the effectiveness of two different theoretical models of motivation to explain why an externally provided rationale often supports students' motivation, engagement, and learning during relatively uninteresting learning activities. Because the predictions made in present study were derived from two theoretical models of motivation, the following sections review these two approaches to understanding when and why externally provided rationales can be expected to promote students' motivation during otherwise uninteresting lessons.

### The Identified Regulation Model

The identified regulation model, derived from self-determination theory (SDT; Deci & Ryan, 1985; Ryan & Deci, 2000) offers one explanation for why an externally provided rationale might facilitate motivation and engagement (see Deci, Eghrari, Patrick, & Leone, 1994; Reeve, Jang, Hardre, & Omura, 2002). SDT explains that when students find a learning activity to be important and personally meaningful to them—even if it is a relatively uninteresting thing to do—they experience a high-quality (i.e., autonomous) type of motivation referred to as “identified regulation” (Deci & Ryan, 1991; Ryan & Connell, 1989). Identified regulation refers to mostly internalized extrinsic motivation, as the individual has identified with the personal importance of an externally prescribed way of thinking or behaving and has thus accepted it as his or her own way of thinking or behaving (Deci & Ryan, 1991). Identified regulation is extrinsic because the activity is performed primarily because of its usefulness or instrumentality (work in order to develop a skill) rather than because it is interesting. It is self-determined because the student engages in the task willingly and for personal reasons rather than by being forced to engage the task because of external pressure. According to SDT's identified regulation model, the reason why an externally provided rationale promotes a student's internalization of task value into autonomous motivation of his or her own is because it provides the student with the information needed to self-identify with the activity as something the self willingly does because it is useful to the self (Deci et al., 1994; Reeve et al., 2002).

Deci et al. (1994) performed a laboratory experiment with a boring computer task (i.e., pressing the space bar on a keyboard whenever a light appeared on the computer screen) in which they manipulated the presence versus absence of three autonomy-supportive factors: a meaningful rationale, acknowledgment of the person's perspective (negative feelings participants might experience while undertaking such an unappealing task), and noncontrolling language that offered choice rather than pressure. The presence of a meaningful rationale did lead participants to perceive the task as an important one (relative to the condition with absence

of rationale). So, by itself, the rationale increased perceptions of task importance. However, when the rationale was communicated with controlling language and without an acknowledgement of the person's perspective, perceived autonomous motivation and extent of engagement were both low. In contrast, when the rationale was communicated with noncontrolling language and with an acknowledgment of negative feelings, autonomous motivation and engagement were both relatively high (Deci et al., 1994). Hence, for a rationale to promote engagement, it must promote not only high task importance but also perceptions of autonomous motivation (i.e., identified regulation).

In extending Deci et al.'s (1994) study, Reeve and his colleagues (2002) used a more academically authentic task to experimentally test whether the provision of a rationale when delivered in an autonomy-supportive way would increase students' effort during an uninteresting (but potentially important) learning activity (i.e., asking preservice teachers to learn conversational Chinese). In this study, identified regulation was conceptualized as a latent variable defined by the pair of indicators of perceived importance of the lesson and perceived autonomy while trying to learn it. In testing this mediation model, participants in the experimental condition were provided with a rationale as to why learning conversational Chinese might be a personally useful thing for them to do (i.e., gain a new teaching skill). Compared with participants not given this rationale, participants given the rationale showed greater effort. A motivational mediation model further showed that the reason why participants with the rationale showed the greater effort was because they felt an identified experience consisting of both a sense of ownership of the task (perceived autonomy) and a sense of task value (perceived importance). Thus, the reason why the externally provided rationale (delivered in an autonomy-supportive way) increased effort was because it allowed participants to experience higher identified regulation during the lesson.

### Interest Regulation Model

The interest regulation model, derived from Sansone and her colleagues' work (Sansone, Weir, Harpster, & Morgan, 1992), offers a second explanation for why an externally provided rationale might facilitate motivation and engagement. The interest regulation model explains that when people find a learning activity to be boring but inevitable, they generally attempt to regulate their interest by self-generating strategies designed to raise their immediate or situational interest to a level that is high enough to get through the otherwise uninteresting endeavor. These self-generated regulatory strategies are called interest-enhancing strategies (IESs; Sansone et al., 1992). Some of the most frequently used IESs include the strategies of setting a goal (Green-Demers, Pelletier, Stewart, & Gushue, 1998), varying the procedure so as to perform the same task in different ways (Sansone, Wiebe, & Morgan, 1999), working in the company of stimulating others such as friends (Isaac, Sansone, & Smith, 1999), and trying to make the task into a game (Wolters, 1998).

To test their hypothesis, Sansone et al. (1992) asked participants to perform a repetitive and boring activity—namely, repetitively copying pages of random letters. Prior to engaging in the boring copying task, participants were either provided or not provided

with a rationale (i.e., performing the task on a regular basis was said to yield health benefits). Sansone et al. predicted that participants performing the copying task with the knowledge of potential health benefits would be most likely to engage in the IESs because they had sufficient reason (the potential health benefit) to expend the effort. Sansone et al. found that hearing a rationale helped participants transform the otherwise boring task into a potentially more interesting one. For example, participants given the rationale performed the copying task more creatively (i.e., less repetitively). This modification, Sansone et al. argued, made the task temporarily more interesting. In a similar (but correlational) study, Wolters (1998) found that college students self-reported more frequent use of IESs to regulate their low motivation during uninteresting academic tasks. These students reported that when they had a strong need to study uninteresting lectures or textbook readings, they became more likely to “make studying into a game” or, simply, “try to make studying more interesting” (Wolters, 1998, p. 229).

Although not studied extensively, there is also evidence linking the use of IESs to greater subsequent effort and persistence. Sansone et al. (1992) found that students who generated an IES in their experimental study persisted longer at the repetitive letter-copying task than did students who did not use such a strategy. Wolters (1999), too, reported a positive correlation between high school students’ reported use of IESs and their degree of not only self-reported effort but also some specific study strategies, such as organization and monitoring.

In interpreting these findings, rationales produce motivational benefits because they prompt people to begin a mental search to find a way to make the uninteresting and unavoidable activity into something tolerable enough to get through it (Sansone & Smith, 2000). That is, when a task is uninteresting and when a rationale deems its performance to be a necessity, people generate more effort-promoting IESs.

## Hypotheses

As reviewed above, two independent explanations have been put forth to explain why externally provided rationales support students’ motivation and engagement. According to SDT, externally provided rationales promote engagement-enhancing identified regulation and internalization of task value into the self-system. According to the interest regulation model, externally provided rationales promote engagement-fostering IESs. Still, although these two different theoretical explanations are informative, it is not yet clear why students show increased engagement during uninteresting tasks in the presence of a rationale. To deepen psychological understanding, the two existing explanations need to be tested further—both independently and in combination with each other.

In the present study, it is hypothesized that, compared with participants not receiving an externally provided rationale, participants receiving an externally provided rationale will display a host of positive outcomes, including motivation, engagement, and conceptual learning. The dependent measures to index the quality of students’ learning experience are as follows. The first four measures assess the quality of students’ motivation and include concepts from both SDT (perceived autonomy, perceived importance) and the interest regulation model (IESs—essay and checklist).

IESs—essay represent the number of IESs participants spontaneously generated on an open-ended question, whereas IESs—checklist represent the number of IESs participants reported using from a prepared checklist of four possible strategies they might have used. The fifth and sixth measures assessed the extent of students’ engagement during the learning activity, as scored by trained raters (observers) during both the first (Time 1) and last (Time 2) 10 min of the learning session. The last two measures assessed the quality of participants’ learning, including measures of both factual and conceptual learning.

The reason why engagement was measured during two different intervals (Time 1 and Time 2) was to detect the enduring effect of the rationale on participants’ engagement over time. As shown in Sansone et al.’s (1992) and Reeve et al.’s (2002) studies, participants with the rationale (vs. its absence) were expected to maintain their task engagement longer compared with participants in the control group, either because IESs made the learning activity more tolerable (Sansone et al., 1992) or because participants identified with the task’s value (Reeve et al., 2002).

As to the two measures assessing the quality of students’ learning, factual learning refers to rote learning and the extent to which participants were able to repeat facts presented during the lesson whereas conceptual learning refers to understanding the core or main ideas discussed during the lesson. I predicted that although participants who receive a rationale will show greater conceptual learning than participants who do not receive a rationale, factual learning will not substantially differ between the two groups. This prediction is based on multiple tests of SDT that have shown that autonomous motivation (e.g., identified regulation) predicts conceptual, but not necessarily factual or rote, learning (Benware & Deci, 1984; Grolnick & Ryan, 1987; Vansteenkiste et al., 2005). This is so because students with autonomous motivation experience a deep, thoughtful, and task-orientated commitment toward learning, and these students process information in a more conceptual and integrative manner, compared with their counterparts. In contrast, these studies report that students with low autonomous motivation still show relatively high factual learning because factual or rote learning requires a more straightforward path to the solution, such as memorization (Benware & Deci, 1984; Grolnick & Ryan, 1987; Vansteenkiste et al., 2005).

To examine why a rationale supports students’ motivation, engagement, and learning during an uninteresting lesson, three possible explanatory models are proposed (see Figure 1). Model 1 depicts SDT’s identified regulation (or internalization) model. It is a motivational mediation model in which the rationale facilitates identified regulation, which, in turn, facilitates engagement, which, in turn, enhances conceptual learning. To operationally define identified regulation as a latent variable, the two indicators of perceived autonomy and perceived importance were assessed (following Reeve et al., 2002). In testing the identified regulation model (Model 1), the present study sought to replicate previous SDT research showing that rationales, when presented in autonomy-supportive ways, facilitate students’ identified regulation (internalization) and engagement. It is important to note, however, that the present study added a learning outcome to test whether the engagement engendered by the rationale and accompanying identified regulation would enhance students’ conceptual

Model 1: Identified Regulation Model

Model 2: Interest Regulation Model

Model 3: Additive Model

Figure 1. Three hypothesized models.

learning. Thus, this learning outcome was an important addition to Reeve et al.'s (2002) identified regulation model.

Model 2 depicts the interest regulation model. It also is a motivational mediation model. In this model, the rationale facilitates interest regulation through the creation and use of IESs, which, in turn, facilitate engagement, which, in turn, enhances conceptual learning. To operationally define interest regulation as a latent variable, I assessed two indicators of the creation and utilization of IESs. The first reported IESs using an open-ended essay format; the second reported the number of IESs checked off of a prepared list of four possible strategies. In testing the interest regulation model (Model 2), the present study sought to replicate previous interest regulation research showing that rationales prompt individuals to create and use IESs. Although the correlation between use of IESs and persistence or extended effort exists, no previous work in this area has experimentally tested the relation that interest regulation has to a learning outcome. Thus, this learning outcome was an important addition to the interest regulation model.

Model 3 depicts an additive model in which the rationale facilitates both identified regulation and interest regulation, both of which, in turn, contribute a unique positive effect on engagement. Further, engagement enhances conceptual learning. This additive model simply combines Model 1 (identified regulation model) and Model 2 (interest regulation model) but, in doing so, allows the key motivational construct from each model to compete to explain the variance in engagement. This will allow a determination of whether identified regulation and interest regulation are additive or whether only one of these motivational processes is sufficient to explain engagement.

## Method

### Participants

Participants included 136 college students (108 women, 28 men) recruited from sections of an introductory educational psychology class at a large Midwestern university. All participants were enrolled in the teacher certification program and were preparing to become teachers after graduation. In exchange for their participation, each participant received extra course credit.

### Uninteresting Activity

The learning activity was selected on the basis of three characteristics: (a) Students would not generally perceive it to be intrinsically interesting, (b) it represented an ecologically valid and school-like lesson, and (c) it possessed hidden value and relevance so that participants could potentially find some personal utility within it. For the uninteresting—yet potentially worthwhile—ecologically valid lesson, I imported a lesson on correlations from an introductory-level statistics textbook for undergraduates (Frederick & Wallnau, 2002). The learning material featured a six-page text-based lesson that covered the following topics: correlation coefficient, scatterplots, correlation and prediction, and correlation and causation. Learning about correlations can be an interesting activity, but for the purposes of the present study, the lesson was presented in an uninteresting format in that it was designed to be both monotonous (following Berlyne, 1966) and void of interest-enhancing embellishments (following Parker & Lepper, 1992). Pilot testing with 32 participants indicated that participants found the lesson to be relatively uninteresting ( $M = 2.17$  on a 7-point

Likert scale with 1 = *not at all interesting* and 7 = *extremely interesting*). The pilot test also confirmed that these 32 participants found 20 min to be an appropriate amount of time to learn the lesson ( $M = 6.25$  on a 7-point Likert scale with 1 = *not at all, too little time* and 7 = *very appropriate*).

### Rationale

An externally provided rationale is a verbal explanation as to why putting forth effort during an activity is a useful and worthwhile thing to do. Past motivation research makes it clear, however, that some rationales are better than others when it comes to engaging students in learning activities. Rationales that are presented in controlling ways ("Do it because I said so" or "Do it because there will be a test") do not help students internalize the value of the activity (Deci et al., 1994; Reeve et al., 2002). In contrast, rationales that are provided in an autonomy-supportive way do help students internalize the value of the activity (Deci et al., 1994; Reeve et al., 2002). For this reason, the rationale manipulation was operationally defined as an externally provided rationale delivered in an autonomy-supportive way. To deliver the rationale in an autonomy-supportive way, I communicated the rationale to participants with both noncontrolling language and the acknowledgement of possible negative feelings.

The content of the rationale used in the present study—namely, that learning correlations is an opportunity to cultivate useful teaching knowledge—was constructed on the basis of rationales offered in several different introductory statistics textbooks explaining the merits of learning about correlations. Once constructed, the rationale was pilot tested with a different group of 35 participants by confirming that they perceived it to be relatively convincing ( $M = 5.78$  on a 7-point Likert scale with 1 = *not at all convincing* and 7 = *very convincing*). The rationale (with embedded noncontrolling language and the acknowledgement of negative feelings) was as follows:

Learning about correlations has been shown to be useful. Those participants who have learned about correlations featured in today's lesson have reported that it helped them become a more reflective teacher. They became more reflective because the lesson learned helps them to see relationships that the naked eye might miss. Correlations summarize vast information to help teachers explore issues, answer questions, solve problems, and make decisions. This is why many educational journals, internet educational websites, and textbooks present information using correlations. For example, a quick glance at the newspaper yields statistics that communicate research findings on new teaching methods, parent-school relations, new instructional technologies, student-teacher relationships, teachers' average income, and so on.

Learning about correlations may not be much fun for some of you. So it is understandable that you might not find it very interesting. Nonetheless, today's lesson is particularly designed to help you think about how two variables might or might not be related to one another or whether one variable predicts or causes the other. Once learned, the correlations featured in today's lesson will open the door for you to gain useful skills, ones that will be very handy when you need to interpret information presented through statistical tools. This is the reason why you are being asked to concentrate, persevere, and try hard on the lesson.

### Procedure

All materials, including the rationale, were presented in booklets. The reason the material was presented in booklets (instead of by an experimenter) was to control for extraneous factors, minimize potential demand characteristics, and increase the study's internal validity (following Deci et al.'s, 1994, research paradigm). Participants were randomly assigned to one of two groups (control condition, experimental condition) and were tested in small groups, with an average of 6 individuals per group. Participants were seated such that they had no contact with other participants. Before the experiment began, all participants completed a consent form and preexperimental questionnaire assessing demographic information.

During the experimental session, two main events occurred. First, the experimenter announced a 3-min introductory period. During this period, the independent variable was manipulated in that each participant received a sheet containing one of two instructions (one with instructions and a rationale, one with instructions and no rationale) according to a random sequence within session. Participants were asked to read the instruction silently. The sheet began with the following general instruction (following Benware & Deci, 1984):

Please use these materials (that you will be given) to learn about correlations. The following topics are covered in the lesson: correlation, correlation coefficient, scatterplots, correlation and prediction, and correlation and causation. Read and study the text materials in the same manner that you would read and study any text assigned in one of your college courses. Please feel free to write on the material or to take notes on the papers provided.

Participants in the experimental condition received additional instruction that included the rationale. Participants in the control condition did not receive this additional instruction.

Second, a 20-min individual learning session followed. During this learning session, all participants received the same six-page booklet of learning materials and were asked to study the materials for 20 min. Participants read and studied silently while working independently and at their own pace. During this period, two trained raters who were naive to the experimental condition independently and surreptitiously scored how behaviorally engaged versus disengaged each participant appeared to be. The raters sat nonintrusively in the corner of the classroom and made independent ratings. The raters scored participants' engagement objectively so that the present study could advance prior studies in this area of research that had used only self-reported engagement scores. After the learning period ended, the experimenter announced that the study time had ended and administered the postexperimental questionnaire. After the postexperimental questionnaires were collected, the experimenter administered an unannounced test to assess learning. Last, all participants received a debriefing.

### Measures

*Identified regulation.* Identified regulation consists of the compound psychological experience of high perceived importance and high perceived autonomy (Reeve et al., 2002). Perceived autonomy was assessed with the nine-item Perceived Autonomy

Scale (Reeve, Nix, & Ham, 2003). The scale has three items to assess an internal perceived locus of causality (e.g., "During the lesson, I felt I was doing what I wanted to be doing"), three items to assess volition (e.g., "During the lesson, I felt free"), and three items to assess perceived choice over one's actions (e.g., "I felt I had control to decide what to do and whether to do it"). Each item used a 7-point Likert scale (1 = *not at all true*, 7 = *very much true*), and scores from these nine items intercorrelated highly enough to average into a single score ( $\alpha = .83$ ). Scores on the Perceived Autonomy Scale have been shown to be valid in that they are sensitive to autonomy-supportive versus controlling teaching styles and predict various measures (self-report, behavioral) of intrinsic motivation (Reeve et al., 2003).

Perceived importance was assessed with a perceived importance scale from a previous study (Reeve et al., 2002). Each of the four items used a 7-point Likert scale (1 = *not at all true*, 7 = *very much true*) with the stem, "Learning the lesson about correlations was . . . : an important thing to do, pointless—a waste of my time (reverse scored), valuable, and worthwhile—it was time well spent. Scores from these four items intercorrelated highly enough to average into a single score ( $\alpha = .87$ ). Scores on this perceived importance scale have been shown to be valid in that they are sensitive to teacher-provided rationales and able to predict engagement during a learning activity (Reeve et al., 2002).

**Interest regulation.** Interest regulation consists of the two indicators of the number of IESs participants reported using during the 20-min study session. The IESs—essay measure used the open-ended question,

During the 20 minute lesson, what did you do to make this learning activity a more interesting thing to do (if anything)? Perhaps you didn't do anything to make the lesson seem more interesting, but if you did use such a strategy, please write your strategy or strategies in the space below.

Two trained independent raters coded the responses using a scoring system derived from empirical work on IESs (following Sansone et al., 1992). From these essays, raters identified and scored the four nominated IESs: (a) set a goal (e.g., "finish prior to a time limit"), (b) used a fantasy context (e.g., "pretended to teach the lesson to someone else"), (c) introduced variety within the task (e.g., "varied how I did the task"), and (d) added stimulation (e.g., "drew a diagram"). Interrater reliabilities were high ( $r = .92$ ), so the raters' scores were averaged into a single score, called IESs—essay.

From pilot testing and from Sansone and colleagues' (1992) work, which IESs participants might use could be anticipated. Hence, a checklist was prepared to score participants' responses on a 4-point scale. The first item asked the participant to check whether or not he or she set a goal: "I set a goal for myself." The second item asked whether the participant used a fantasy context: "I imagined, pretended, or fantasized myself teaching or explaining this material to someone (e.g., my students)." The third item asked whether the participant introduced variety within the task: "I varied the task in some way (e.g., by switching my attention from one part of the text to another part)." Last, the fourth item asked whether the participant added stimulation: "I drew a picture or diagram to stimulate or entertain myself." Participants were asked to check off which specific strategies they used among the four listed. Checking any one individual strategy constituted a separate

point on the scale. For instance, a student who reported using a fantasy context but not goal setting, variety, or stimulation scored a 1 on the IESs—checklist measure. The checklist appeared on the postexperimental questionnaire after participants had already completed the open-ended essay question.

To validate both measures, participants completed a three-item self-report measure of interest (Williams, Wiener, Markakis, Reeve, & Deci, 1994). Each item used the same 7-point response scale (1 = *not at all true*, 7 = *very much true*) with the stem, "Please rate 'learning about correlations' as an activity:" it held my full and constant attention, it stimulated my curiosity without interruption, and it was very interesting. These three items were averaged into a single score for interest ( $\alpha = .90$ ). This measure has been shown to be valid in that scores predict behavioral measures of intrinsic motivation (Reeve, 1989) and career choice decisions (Williams et al., 1994). In the present study, this self-report interest measure correlated significantly with the use of IESs as reported on both the essay,  $r(136) = .34, p < .01$ , and checklist,  $r(136) = .26, p < .01$ , measures. These positive correlations are important because they confirm that the degree to which these strategies were used was positively associated with interest.

**Engagement.** Raters scored three aspects of participants' engagement during the lesson (based on Skinner & Belmont, 1993): on-task attention, effort, and persistence. To score these three behavioral expressions of engagement, two trained raters used a rating sheet with 7-point bipolar scales. For on-task attention, the bipolar descriptors were dispersed—off task (scored as 1) versus focused—on task (scored as 7). For effort, the bipolar descriptors were passive, slow, or minimal effort (scored as 1) versus active, quick, or intense effort (scored as 7). For persistence, the bipolar descriptors were gives up easily during challenge, failure, or confusion (scored as 1) versus persistent (scored as 7). During the 20-min lesson, two trained raters who were naive to the experimental condition independently made two separate ratings—one during the first 10 min and the second during the last 10 min. The reason why engagement was measured during two different times was, as mentioned earlier, to detect the effect of the rationale on engagement over time.

For both rating periods, raters' scores correlated highly with one another. The intercorrelations between the two raters at Time 1 (first 10 min) were as follows: attention,  $r = .76, p < .01$ ; effort,  $r = .75, p < .01$ ; and persistence,  $r = .76, p < .01$ . The intercorrelations between the two raters at Time 2 (last 10 min) were as follows: attention,  $r = .90, p < .01$ ; effort,  $r = .88, p < .01$ ; and persistence,  $r = .86, p < .01$ . Because interrater reliabilities were high, the pairs of scores from the two raters were averaged to form a single score for attention, effort, and persistence at each time period. Once done, the three engagement ratings (attention, effort, and persistence) were averaged into the two following engagement scores: engagement at Time 1 (three items,  $\alpha = .96$ ) and engagement at Time 2 (three items,  $\alpha = .97$ ).

**Learning.** Following Benware and Deci (1984), the dependent measure to assess the two types of learning was scored from a 14-item multiple-choice examination. Each question was designed to measure either factual learning or conceptual learning of the material. To construct this measure, experts in the statistics department at a major university read the text and created 14 factual questions to assess recognition of facts and 14 questions to assess conceptual understanding of the information. Two expert raters

then independently scored each question categorically as either a factual question or a conceptual question. Only those items that received an identical factual–conceptual classification by the two experts were used in the study. The final test featured seven factual questions and seven conceptual questions. An example of a factual learning question was, “A correlation coefficient indicates the . . .” (followed by four response options). An example of a conceptual learning question was, “Which of the following questions is best suited for correlational research?” (followed by four response options). Possible scores for both the factual learning test and the conceptual learning test could range from 0 to 7.

## Results

Descriptive statistics for the eight dependent measures appear in Table 1, broken down by experimental condition. A series of *t* tests was used to test for mean differences between the experimental and control groups. To conduct seven independent tests (eight dependent measures minus factual learning) and still protect against making a Type 1 error, I calculated what each testwise alpha level must be to produce an overall experimentwise (exp) alpha level of .05. With seven tests, the  $\alpha_{\text{exp}}$  was inflated to .30 (using  $\alpha_{\text{test}} = .05$ , one-tailed; based on Hays’s, 1984, formula of  $\alpha_{\text{exp}} = 1 - [1 - .05]^7$ ). So, to readjust the inflated .30  $\alpha_{\text{exp}}$  back down to .05, I computed what each  $\alpha_{\text{test}}$  needed to be for each correlation test. This value was .014 (based on Hays’s, 1984, formula of  $\alpha_{\text{test}}/\text{number of tests}$ , or  $.05_{\text{one-tailed}}/7$ ). Because my hypotheses were directional, using a one-tailed test was both more suitable and more powerful (Hopkins, Glass, & Hopkins, 1987; Minium, King, & Bear, 1993).<sup>1</sup> Prior to conducting these *t* tests, I first explored whether gender influenced any motivation, engagement, or learning measure. A series of *t* tests were performed, and results showed that gender did not influence any of the study’s eight dependent measures. The data for each dependent measure were therefore collapsed across gender.

The provision of an externally provided rationale enhanced motivation, and this was true for all four measures, including perceived autonomy ( $d = 0.55$ ), perceived importance ( $d = 0.71$ ), IESs–essay ( $d = 0.56$ ), and IESs–checklist ( $d = 0.42$ ). The provision of an externally provided rationale enhanced engagement, and this was true for both engagement at Time 1 ( $d = 0.44$ ) and engagement at Time 2 ( $d = 0.64$ ). For learning, the provision of an externally provided rationale enhanced conceptual learning ( $d = 0.39$ ) but not factual learning.

### *Effect of the Rationale on Engagement Over Time*

As reported, raters scored the participants who received the rationale as significantly more engaged during the 20-min lesson than participants who did not receive the rationale. To test whether the rationale supported an engagement-fostering benefit over time, I performed a repeated-measures analysis using the presence versus absence of the rationale as the between factor and the rating period (Time 1, Time 2) as the within factor. Both the rationale,  $F(1, 134) = 13.08$ ,  $p < .001$ , and the rating period,  $F(1, 134) = 140.63$ ,  $p < .001$ , were individually significant, as the rationale facilitated engagement and engagement decreased over time. Of more importance, however, the Rationale  $\times$  Rating Period interaction effect was significant,  $F(1, 134) = 7.72$ ,  $p < .01$ , as the rate

of disengagement from the uninteresting lesson for participants in the control group was significantly more pronounced than it was for participants who received the rationale, as shown in Figure 2. This is an important finding because it indicates that the motivational benefits from the rationale (i.e., identified regulation, interest regulation) became increasingly important to sustaining engagement as the lesson continued over time.

### *Test of Hypothesized Models*

The three hypothesized models were tested with structural equation modeling using LISREL 8.51 (Jöreskog & Sörbom, 2001). To test the fit of the data to the hypothesized models, I followed the two-step approach recommended by Anderson and Gerbing (1998). First, to determine whether the indicators related satisfactorily to the latent variables, I performed a confirmatory factor analysis to assess the fit of the measurement model. Second, the series of three hypothesized models (see Figure 1) were tested as structural models. To evaluate the fits of the measurement and structural models, I relied on a set of five test statistics. Traditionally, a nonsignificant chi-square serves as the basic test of whether a model adequately describes the data (Bollen & Long, 1993); however, I further included a set of fit indices because they often provide a better evaluation of model fit than does the chi-square statistic (Bentler & Bonett, 1980; Marsh, Balla, & McDonald, 1988). Those four fit indices were the root-mean-square error of approximation (RMSEA), the root-mean-square residual (RMR), the nonnormed fit index (NNFI), and the comparative fit index (CFI). RMSEA and RMR are summary statistics for the residuals, so the lower the number, the better (i.e.,  $\text{RMR and RMSEA} < .05$ , down to a possible low of 0; Hu & Bentler, 1999). NNFI and CFI compare the lack of fit of the theoretical model to the independence model, so the higher the number, the better (i.e.,  $\text{NNFI and CFI} > .95$ , up to a possible high of 1; Hu & Bentler, 1999).

According to the chi-square statistic and the goodness-of-fit indices, the measurement model fit the observed data well,  $\chi^2(9, N = 136) = 5.58$ , *ns*,  $\text{RMSEA} = .00$ ,  $\text{RMR} = .03$ ,  $\text{NNFI} = 1.00$ ,  $\text{CFI} = 1.00$ . In examining the parameter estimates, each measure–indicator loaded significantly and positively on its appropriate latent factor.

To conduct the main structural model analyses, I categorically scored the provision of a rationale—the manipulated predictor variable—as 0 for absence of a rationale and as 1 for the provision of a rationale. Means, standard deviations, and intercorrelations among the eight measures included in the hypothesized models appear in Table 2.

**Hypothesized Model 1.** The identified regulation model proposed that the rationale would enhance participants’ identified regulation, which would increase participants’ engagement, which, in turn, would enhance their learning (see Figure 3). This model fit the

<sup>1</sup> One-tailed tests were used because participants’ initial orientation to the lesson in terms of motivation and prior knowledge in both groups (experimental vs. control) was already low. Hence, it was doubtful that participants who received a rationale in the present study would show a significant decrease in these items compared with participants in the control group. Also, no previous study has shown that participants with a rationale scored lower on a measure of motivation, engagement, or learning than did participants without a rationale (Benware & Deci, 1984; Deci et al., 1994; Reeve et al., 2002; Sansone et al., 1992).

Table 1  
Means (and Standard Deviations) for Each Dependent Measure by Experimental Condition

Dependent measure	Possible range	Experimental condition		<i>t</i> (134)
		Rationale absent ( <i>n</i> = 67)	Rationale present ( <i>n</i> = 69)	
Perceived autonomy	1-7	4.28 (1.07)	4.87 (1.07)	3.57*
Perceived importance	1-7	3.89 (1.22)	4.66 (0.94)	4.30*
Interest-enhancing strategies—Essay	0-4	0.38 (0.52)	0.69 (0.58)	3.26*
Interest-enhancing strategies—Checklist	0-4	0.99 (0.86)	1.35 (0.84)	2.49*
Behavioral engagement, Time 1	1-7	5.44 (1.10)	5.86 (0.81)	2.50*
Behavioral engagement, Time 2	1-7	3.70 (1.66)	4.72 (1.51)	3.73*
Factual learning	1-7	5.70 (1.27)	6.07 (1.18)	1.76
Conceptual learning	1-7	5.27 (1.45)	5.87 (1.14)	2.69*

\*  $p < .014$ .

observed data well,  $\chi^2(7, N = 136) = 2.65$ , *ns*, RMSEA = .00, RMR = .02, NNFI = 1.00, CFI = 1.00. As shown in Figure 3, each of the hypothesized paths within the identified regulation model was significant and in the predicted direction, as the rationale predicted identified regulation ( $\beta = .42$ ,  $p < .01$ ), and identified regulation predicted engagement ( $\beta = .33$ ,  $p < .01$ ), which, in turn, predicted learning ( $\beta = .45$ ,  $p < .01$ ). Further, the direct (unmediated) path from the rationale to engagement was not significant ( $\beta = .19$ , *ns*), showing that identified regulation, rather than the provision of the rationale per se, best explained extent of engagement. The overall identified regulation model explained 19% of the variance in engagement and 20% of the variance in learning.

**Hypothesized Model 2.** The interest regulation model proposed that the rationale would enhance participants' interest regulation, which would increase their engagement, which, in turn, would enhance their learning (see Figure 4). This model fit the observed data well,  $\chi^2(7, N = 136) = 6.54$ , *ns*, RMSEA = .00, RMR = .04, NNFI = 1.00, CFI = 1.00. As shown in Figure 4, each of the hypothesized paths within the interest regulation model was significant and in the predicted direction, as the rationale predicted interest regulation ( $\beta = .41$ ,  $p < .01$ ), and interest regulation predicted engagement ( $\beta = .25$ ,  $p < .01$ ), which, in turn, predicted learning ( $\beta = .44$ ,  $p < .01$ ). However, unexpectedly, the direct path from the rationale to engagement remained significant ( $\beta = .22$ ,  $p < .05$ ),

Figure 2. Effects of rationale and rating period on participants' engagement.

Table 2  
Descriptive Statistics and Intercorrelation Matrix for all Dependent Measures Included in Hypothesized Models

Dependent measure	M	(SD)	1	2	3	4	5	6	7	8
1. Rationale	0.51	(0.50)	—							
2. Perceived autonomy	4.57	(1.00)		—						
3. Perceived importance	4.28	(1.10)			—					
4. Interest-enhancing strategies—Essay	0.54	(0.57)				—				
5. Interest-enhancing strategies—Checklist	1.17	(0.87)					—			
6. Behavioral engagement, Time 1	5.65	(0.98)						—		
7. Behavioral engagement, Time 2	4.42	(1.66)							—	
8. Conceptual learning	5.57	(1.33)								—

Note. The possible range for each dependent measure was from 1 to 7, except for Measures 4 and 5; the possible range for these measures was from 0 to 4. *N* = 136. \* *p* < .05, one-tailed. \*\* *p* < .01, one-tailed.

showing that interest regulation only partially mediated the effect that the provision of a rationale had on engagement. The overall identified regulation model explained 16% of the variance in engagement and 20% of the variance in learning.

**Hypothesized Model 3.** The additive model proposed that the rationale would enhance both participants' identified regulation and interest regulation (see Figure 5). This model further predicted that both identified regulation and interest regulation would each contribute uniquely and positively to predicting participants' engagement. Finally, the additive model predicted that extent of engagement would predict learning. The additive model fit the observed data well,  $\chi^2(15, N = 136) = 9.05, ns$ , RMSEA = .00, RMR = .03, NNFI = 1.00, CFI = 1.00. As shown in Figure 5, the rationale significantly predicted both identified regulation ( $\beta = .41, p < .01$ ) and interest regulation ( $\beta = .41, p < .01$ ). In the prediction of engagement, however, identified regulation predicted engagement ( $\beta = .32, p < .01$ ) but interest regulation did not ( $\beta = .02, ns$ ). Further, the direct (unmediated) path from the rationale to engagement was not significant ( $\beta = .18, ns$ ). The overall additive model explained 19% of the variance in engagement and 20% of the variance in learning. Of note, the key motivational constructs were not additive in the effects on engagement; when they competed for variance, only identified regulation predicted engagement.

**Conclusion.** All three structural models fit the data equally well, all three models accounted for a comparable amount of the

variance in both engagement and learning, and no model fit the data significantly better than did another. The reason why Model 2 is the less favored model is because it needed the rationale to explain engagement, whereas Models 1 and 3 did not. As shown in Model 3, the reason why rationale predicted engagement in Model 2 was because the rationale facilitated the identified regulation process. Hence, although all three models fit the data comparatively well, the pattern of significant and nonsignificant paths to engagement made it clear that engagement was facilitated by identified regulation and not by interest regulation.

Discussion

Recognizing that an externally provided rationale can promote students' motivation and engagement during an uninteresting lesson, the present study sought to provide a theoretical and comprehensive understanding of the functional motivational significance that an externally provided rationale can have on students' engagement and learning. Findings showed that an externally provided rationale, when delivered in an autonomy-supportive way, promoted a relatively high-quality learning experience for participants, as assessed by their motivation, engagement, and conceptual learning (see Table 1). These findings confirm past research findings showing the motivational benefits of externally provided rationales during uninteresting learning activities. Findings in the

present study further allow psychologists to answer the question of why such rationales generate these benefits.

#### *Why a Rationale Supports Students' Motivation, Engagement, and Learning*

The empirical test of the identified regulation model (see Figure 3) showed that the identified regulation model fit the data well. Accord-

ing to SDT, rationales facilitate engagement and learning because a rationale, when communicated in an autonomy-supportive way, reveals an activity's value and personal benefit (Ryan & Deci, 2000, 2002). Such personal relevance information helps participants identify with and internalize the value of the task (identified regulation), and this internalization allows participants to engage volitionally in the learning activity. Thus, although the activity itself was inherently uninteresting, the externally provided rationale facilitated

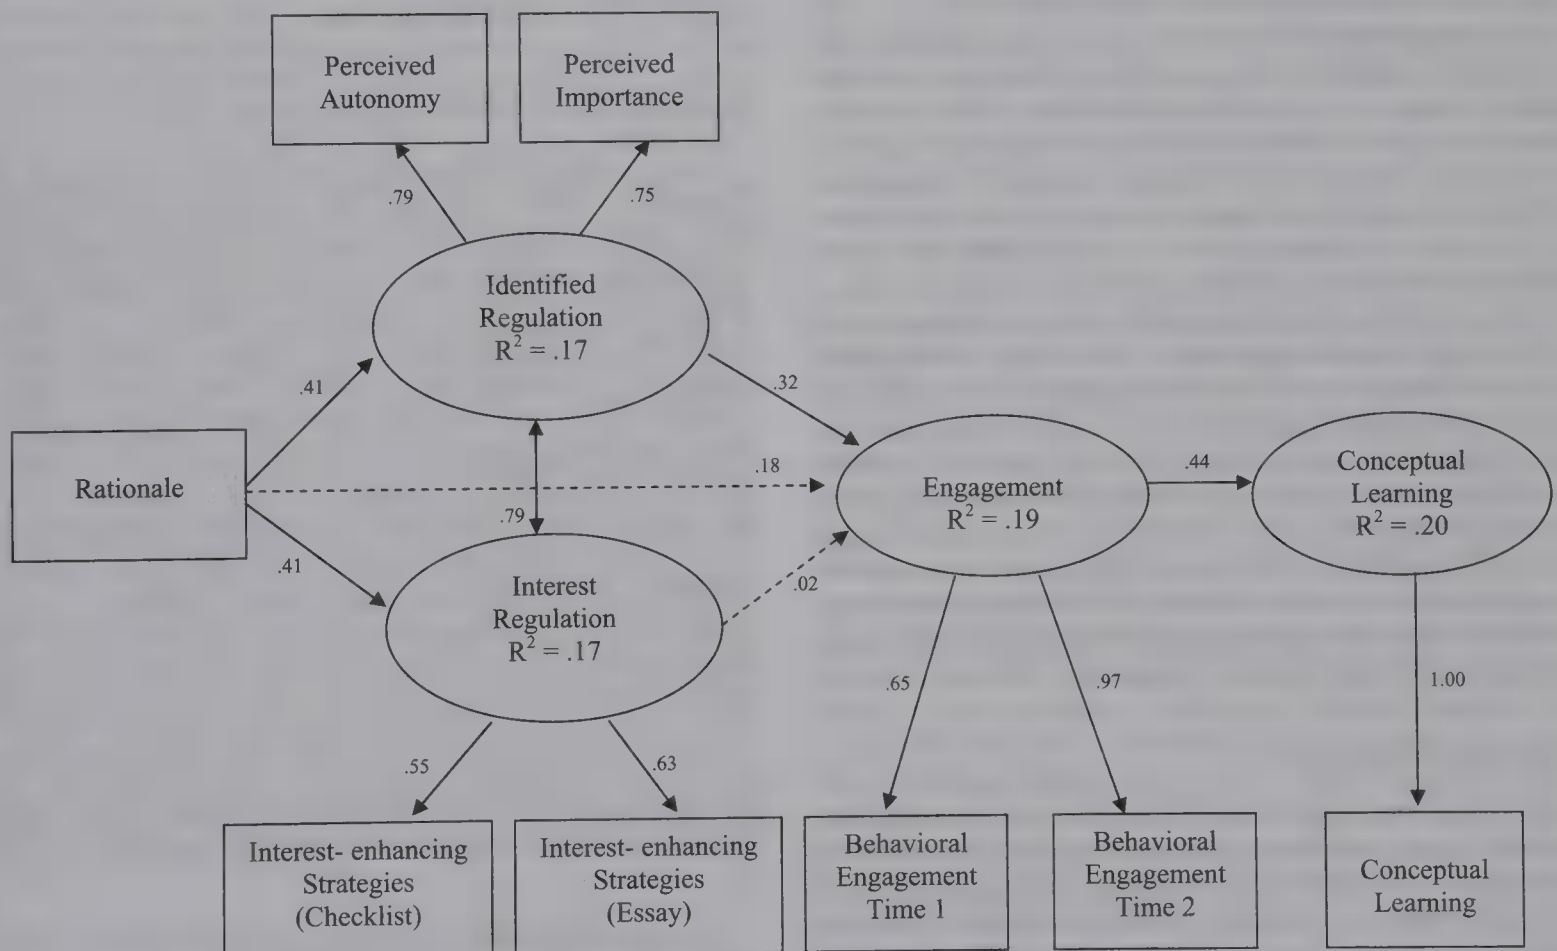

Figure 5. Standardized parameter estimates from the LISREL analysis of Model 3: the additive model. Solid lines represent significant paths,  $p < .05$ ; dashed lines represent nonsignificant paths.

participants' capacity to take on the externally provided rationale as their own self-endorsed reason to try hard. Once experienced, identified regulation was largely an engagement-fostering process, and extent of engagement explained learning.

The empirical test of the interest regulation model (see Figure 4) also fit the observed data well. According to the interest regulation model (Sansone et al., 1992), rationales facilitate engagement and learning because a rationale helps participants see the otherwise uninteresting activity as a necessary undertaking. Perceiving an uninteresting activity as a necessity prompts people to generate the IESs they need to make the activity tolerable. Although interest regulation did promote engagement, the rationale unexpectedly exerted a direct effect on engagement as well. This means that interest regulation explained only part of the reason why the rationale promoted engagement. Examination of the additive model revealed the reason why the rationale continued to exert a direct effect on engagement in the interest regulation model—namely, because this model did not include the important motivational mediating variable of identified regulation.

The empirical test of the additive model (see Figure 5) showed that the additive model fit the data well. As expected, the provision of a rationale promoted both identified regulation and interest regulation. When both these effects were considered together, the identified regulation effect on engagement was significant whereas the interest regulation effect was not. That is, adding the interest regulation path to engagement did not allow the additive model to explain any additional variance in engagement (or learning) beyond that explained by the identified regulation model itself. Hence, the additive model simply restates the identified regulation model but adds the tangential path from the rationale to enhanced interest regulation.

The findings reported for the additive model suggest that the reason why interest regulation has predicted task persistence in previous studies (Sansone et al., 1999; Werner & Makela, 1998) is probably because of the close association IESs have with identified regulation ( $\beta = .79, p < .01$ ; see Figure 5). Hence, although IESs help make an otherwise uninteresting learning experience more tolerable (less boring), they do not necessarily enhance engagement above and beyond the engagement-fostering properties of identified regulation. This is not to say that interest regulation does not play a meaningful role in the experience of uninteresting lessons. For instance, the use of IESs was significantly correlated with relatively high interest. Such a gain in positive emotion and subjective well-being is important and meaningful for its own sake. However, in the present study, interest regulation did not serve as an independent (unique) engagement-fostering strategy. This interpretation is consistent with Burton, Lydon, D'Alessandro, and Koestner's (2006) finding that identified regulation uniquely predicts effort and achievement (but interest regulation does not), whereas interest regulation uniquely predicts psychological well-being (but identified regulation does not).

### *Classroom Implications*

To facilitate students' motivation, rationales need to produce two effects: Students need to see the importance and personal utility within the task, and students need to perceive high autonomy while working on that task. The content of an externally provided rationale accomplishes the first purpose, whereas the way it is communicated—in an autonomy-supportive way—accomplishes the second purpose. When rationales are communicated in an autonomy-

supportive way, students are more likely to perceive the utility message within the rationale as a conduit for autonomy support. That is, students are likely to view the purpose—the functional significance (Deci & Ryan, 1991)—of the rationale as an external contingency intended to support their autonomy. If the same rationale were not delivered in an autonomy-supportive way, then it would not be expected to facilitate autonomy and hence identified regulation. The present study did not test this later assertion, but previous work by Deci and his colleagues (1994) shows that when rationales are presented in controlling ways, they fail to engender engagement-fostering benefits.

The provision of an externally provided rationale gives teachers an instructional strategy capable of fostering autonomous motivation, engagement, and subsequent learning during those lessons that teachers expect students might find relatively uninteresting. Being an external contingency, the rationale promotes extrinsic motivation but does so in a way that supports congruence between students' subjective feelings and their behavior directed toward the task. Most extrinsically motivating instructional strategies, such as extrinsic rewards, typically induce students into a compliance mode that places their subjective feelings ("this is boring") at odds with their engagement behavior (Joussemet, Koestner, Lekes, & Landry, 2005). Extrinsically motivating instructional strategies enhance engagement best when they allow harmony or congruence between students' inner motivational resources ("I want to do this") and their task engagement (spending 20 min studying the lesson). The externally provided rationale used in the present study worked as an effective extrinsically motivating strategy because it allowed students' experience of autonomous motivation (perceived importance, perceived autonomy) to be the motivational foundation that determined the extent of their task engagement and subsequent learning.

### *Implications for Subjective Task Values*

Value researchers emphasize three major contributors to (or components within) subjective task value: (a) extrinsic utility value, which is a task's perceived usefulness in accomplishing some desired end state, such as a career goal; (b) interest value, which is the task's perceived capacity to generate a sense of enjoyment; and (c) attainment value, which is a task's sense of importance to the individual's underlying self-system (Eccles & Wigfield, 1995).<sup>2</sup> Because this research has relied almost exclusively on nonexperimental survey-based research, the teacher's potential role in enhancing students' valuing of classroom activities has been largely unexplored (as researchers typically examine how privately held values correlate with task choices, such as whether or not to take a math class; Meece, Wigfield, & Eccles, 1990). The present findings therefore can potentially offer some unique insights into the process in which educators attempt to transfer objective task value (what the school values) to subjective task value (what the student values; Eccles & Wigfield, 1995).

Translating these three contributors to subjective task value into the concepts featured in the present experimental research aligns extrinsic utility value with the contents of the externally provided

<sup>2</sup> In addition to these three contributors, additional components, such as costs, subject matter appreciation, and/or future goals, are also possible contributors to subjective task value (Brophy, 1999; Husman & Lens, 1999; Miller & Brickman, 2004; Wigfield & Eccles, 1992).

rationale, interest value with interest regulation, and attainment value with identified regulation. To the extent that these concepts are interchangeable, three insights emerge in regard to the educational effort to promote students' subjective task value during uninteresting academic lessons.

First, the effort to directly communicate a task's extrinsic utility value to students can be expected to fail more often than not. This skepticism stems from previous rationale-based research showing that externally provided rationales that communicate only a task's extrinsic utility value fail to promote either internalization or engagement in their recipients (Deci et al., 1994; Reeve et al., 2002). Before the extrinsic utility value information contained within a teacher-communicated rationale can be expected to promote either internalization or engagement, it first needs to be embedded within an autonomy-supportive communication style—one that takes the perspective of students, acknowledges their negative feelings, and relies on informational language. To the extent that teachers do not make the instructional effort to help students find personally meaningful connections between their own goals, values, and sense of self and the classroom's uninteresting learning activities, the extrinsic utility value information within a rationale will likely generate only external regulation (not engagement-fostering identified regulation, which is autonomous extrinsic motivation; Reeve et al., 2002). Second, attainment value lies fully within the eyes of the student—in the student's sense of self. Hence, teacher-initiated instructional strategies to promote students' attainment value toward an uninteresting task make little sense. Instead, the most promising engagement-fostering instructional strategy during an uninteresting task appears to be to blend high awareness of what students already value with externally provided rationales to explain the interrelationship between the student's sense of self and the utility value offered by the task. Such an approach characterizes the independent variable used in the present study—namely, using an autonomy-supportive communication style to explain the task's extrinsic utility value to the student's sense of self (as a prospective teacher). This conclusion has potential application not only for promoting value in uninteresting lessons but also for promoting valuing in students' long-term future goals as well (Husman & Lens, 1999; Miller & Brickman, 2004). That is, the effort to promote another's active engagement toward a long-term future goal likely requires both autonomy support to foster self-determined attainment value and explanatory rationales to promote a specific activity's utility value. Third, the findings show a surprising lack of support for the instructional effort to promote interest value during uninteresting activities. Under circumstances in which students are very likely to be extrinsically motivated—because the task itself cannot provide the inherent satisfactions students need to experience intrinsic motivation—IESs were unable to generate the type of motivation students needed to freely engage in and learn from the deeply uninteresting lesson they faced. When tasks are deeply uninteresting, providing rationales in an autonomy-supportive way to promote identified regulation seems to be the more promising engagement-fostering strategy.

### *Future Research*

The findings point to a number of potentially fruitful areas for future research. Rationales produce positive motivational benefits

because they help students perceive the otherwise hidden utility within the uninteresting activity, such as the capacity of the activity to help them develop an important skill. In practice, then, teachers need to communicate to students how they can benefit from the uninteresting tasks that are assigned to them. One question for future research is the extent to which teachers actually attempt to do this. It remains to be studied whether teachers generate the sort of rationales that their students will accept and internalize. Another question to ask is how successful teachers typically are in helping their students internalize the externally provided rationales they hear into self-endorsed reasons of their own. Another question to ask is what qualities of a rationale are most likely to help students accept it as their own. In other words, what qualities allow some rationales to be perceived as convincing and satisfying whereas other rationales are perceived as bogus, empty, or even manipulative? Still another question to ask is whether the effectiveness of a rationale depends somewhat on students' preexisting identified regulation toward the type of activity that includes the target activity. Can a teacher provide an otherwise amotivated student with a convincing and satisfying rationale and see that student begin to experience some level of identified regulation toward that task? Or, does the effectiveness of an externally provided rationale depend on the presence of some preexisting amount of students' identified regulation in that area of study?

Another question for future research is to explore students' capacity to self-generate rationales. It is not at all clear how rare or how commonplace the practice of self-generating a rationale is during academic lessons. It is also an unanswered question whether student-generated rationales might be more motivationally productive than teachers' externally supplied rationales. On the one hand, student-generated rationales would supposedly be richly embedded within their high identified regulation toward the lesson, whereas, on the other hand, a teacher's externally generated rationale would have the advantage and insight of an experienced expert as to what hidden use underlies the enactment of the uninteresting task.

It is also worth clarifying what interest regulation during an uninteresting task is not. IESs to regulate one's interest are not strategies to escape from or avoid uninteresting tasks. An IES does not, for instance, take the student away from the academic task and toward a substitute (and more interesting) alternative, such as daydreaming (off-task IESs). Time spent daydreaming would lower the student's on-task engagement for the academic assignment and hence decrease learning, performance, or skill development. This is why the inclusion of the currently absent behavioral measures of engagement and measures of learning or performance are so important in the conduct of interest regulation research. Future research on interest regulation needs to show that the IES does not undermine performance. Instead, an academically worthwhile IES is one in which the activity to be done remains the same—read the 200-page book, complete the 20 homework questions, or learn the periodic table. What changes is not the lesson but the students' interest while engaged in the lesson. Students have the capacity to create and use IESs, and, in doing so, they experience the benefit of positive emotion and subjective well-being. Future research on interest regulation and IESs might perhaps reveal additional benefits of these strategies. For instance, the large covariation between identified regulation and interest regu-

lation (see Table 2 and Figure 5) raises the possibility that interest regulation, like the provision of a rationale, might function as a facilitating path to enhanced internalization and identified regulation. In pursuing such a research question, future research might investigate the theoretical and conceptual link between IESs and subsequent identified regulation.

A next step in this line of research is to test these hypothesized models using classroom teachers communicating with students, parents communicating with their children, and school counselors communicating with students. In these naturalistic settings, many different rationales are communicated, which raises the question, "What constitutes an effective rationale?" In the present study, I designed the rationale to facilitate two correlated effects: (a) enable the participant to perceive the activity as important enough to become worth one's effort and (b) help the participant make a connection between the activity and a personal goal (i.e., gaining a useful skill in the present study). In this same spirit, Deci and his colleagues (1994) conceptualized an effective rationale as that which is personally meaningful. The phrase "personally meaningful" nicely captures the experience that lies at the intersection of perceived autonomy and perceived importance.

### Limitations

The primary limitation of the present study was that it was not carried out within the context of an on-going classroom environment. Because the rationale was communicated in a written form (to control for extraneous factors), there was no interpersonal relationship between the rationale provider (e.g., a teacher) and its recipients (e.g., students). Within the context of an on-going interpersonal relationship, each of the following qualities in the teacher trying to motivate students has been found to contribute positively to the students' willingness to accept (i.e., internalize) the communicated rationale: warmth (Goodenow, 1993; Midgley, Feldlaufer, & Eccles, 1989), involvement (Skinner & Belmont, 1993), and interpersonal relatedness (Ryan & Powelson, 1991). Presumably, providing a rationale within the context of a warm, caring relationship would produce a stronger effect on students' motivational processes. Thus, the effects obtained in the present study probably underestimate the motivation-enhancing possibilities of teacher-provided explanatory rationales. To test whether this is so, additional research in actual classroom settings is needed. In addition, because only college-age students were used, the applicability of these findings to the younger grade school children remains untested.

# College Seniors' Theory of Their Academic Motivation

Shawn Van Etten  
University of Massachusetts at Dartmouth

Michael Pressley  
Michigan State University

Dennis M. McInerney and Arief Darmanegara Liem  
Nanyang Technological University

College seniors participated in an ethnographic interview study about their academic motivations. It was found that grades and graduation are 2 primary distal target goals that motivate their academic efforts during the senior year. A variety of proximal factors were also reported to affect the seniors' motivation. These factors can be divided into students' internal and external factors. Among the internal factors are student characteristics (e.g., social class, expectations) and student beliefs (e.g., belief about control, belief about learning and mastery), whereas the external factors comprise academic-related factors (i.e., course-, examination-, and assignment-related characteristics, reward, and feedback), social factors (i.e., instructors, family members, and peers), general college environment (i.e., physical environment, academic associations, and internship/volunteer opportunities), and extracurricular activities (i.e., fraternities/sororities and sports participation). These results suggest that there is much to learn about academic motivation during the college years. In particular, there is a need for research employing methodologies other than quantitative, survey-based method that can capture the complexities of motivation during college.

**Keywords:** motivation, strategies/tactics, metacognition, higher education, ethnographic interviewing coupled with the method of constant comparison

Many of the recent studies addressing academic motivation have employed an a priori theoretical approach to the identification of students' motivational constructs and how they regulate the students' achievement related functioning and outcomes (see, e.g., Brophy, 2004; Schunk, Pintrich, & Meece, 2008; Stipek, 2002, for recent reviews). Typically, this has meant that researchers have postulated, in advance, the existence of certain motivational constructs, such as academic goal orientations (Covington, 2000; Elliot, 2005; Kaplan & Maehr, 2007; Pintrich, 2000), attributions of success and failures (Weiner, 2004), self-worth (Covington, 2004), self-efficacy (Bandura, 1997; Schunk & Pajares, 2005), future goals (McInerney, 2004; Nurmi, 1991; Phaet, Andriessen, & Lens, 2004; Simons, Vansteenkiste, Lens, & Lacante, 2004), and task value and expectancy for success (Eccles & Wigfield, 1995; Wigfield & Eccles, 2000; Wigfield, Tonks, & Eccles, 2004), and they have attempted to validate these preconceived constructs

through the use of psychometric research techniques, including testing the hypothesized relationships among constructs (Bong, 1996; Pintrich, Conley, & Kempler, 2003). Such an approach to investigating students' academic motivation may, however, (a) constrain researchers from studying other important motivational constructs and their interactions with external, environment factors and (b) fail to elucidate the relationships of these constructs, both among the constructs themselves and between the constructs and their cognitive, behavioral, and affective concomitants (Pintrich, 2000, 2003; Pintrich et al., 2003). In other words, such quantitative investigations may misrepresent the complexity and dynamism of students' academic motivation.

The present study aims to map out the macrovariables potentially affecting academic motivation of college seniors on a day-to-day basis. Since there has been a long history of research investigating academic motivation, we come to this study with certain theoretical sensitivities about the nature of academic motivation in college students emanating from the extant literature that goes back some 40 years ago (e.g., Becker, Geer, & Hughes, 1968, 1995). That literature also makes apparent, however, that there is an important theory-generating role for qualitative research (Strauss & Corbin, 1990, 1997), including in the area of academic motivation of college students, in particular, in identifying motivational variables that are salient in their lives that might have previously been overlooked by researchers.

## Theoretical Sensitivities

As early as the late 1950s, sociologist Howard Becker and his associates conducted a landmark study on the nature of undergrad-

uate studentship (Becker et al., 1968, 1995). An overarching goal for their study was to understand the college experience from the perspective of the students. Becker et al.'s (1968, 1995) primary methodology was participant observation, which meant in that study that the investigators followed students around for long periods of time, observing what they did and asking them questions about the meanings of the actions observed.

One of Becker et al.'s (1968, 1995) major conclusions was that the grade point perspective predominated in the thinking of undergraduate students—that the students were constantly concerned about their grades, for example, fearing that low grades would exclude them from professional school or prevent them from obtaining the best available jobs. The grade point perspective documented by Becker et al. comprised seven subperspectives (Becker et al., 1995, p. 34):

- (1) . . . rewards that students desire cannot be achieved without sufficiently high grades; (2) a successful student . . . will "do well" in his [or her] academic work; (3) doing well in academic work . . . consists of getting a "good" grade point average; (4) . . . where the actions necessitated by the pursuit of grades conflict with other interests, the latter must be sacrificed; (5) to be successful, a student should do whatever is necessary to get "good" grades, not expending effort on any other goal . . . until that has been achieved; (6) . . . grades can be used to judge the personal worth of other students and of oneself; (7) faculty members may be judged . . . according to how difficult they make it to achieve adequate or "good" grades.

In short, Becker et al. (1968, 1995) viewed grades as the "chief institutionalized valuable of the college" (p. 55). It was true that in their study some students thought that learning for its own sake and personal and intellectual development was important, but many more students (indeed most) valued grades above all else. Using a historiographical method, a historian of higher education Horowitz (1987) made the case that grades have been a principal, if not the principal, motivation of American college students at least since the 1700s, and thus supported Becker et al.'s conclusion. Further, the importance of grades as motivators in the eyes of college students was also demonstrated in more recent studies underpinned by different social science perspectives, including those by Abouserie (1994), Michael (1991), Wolters (1998), and Zitzow (1984).

That said, an alternative perspective is that motivation for grades is only one of many variables affecting academic motivation. McKeachie (1961), for example, made the intuitive case that college student motivation depended on many factors, including teaching methods, learning styles and motives, and teaching method by learning style (motive) interactions. It is true that McKeachie agreed that an overarching goal was grades, because they determined in part whether students could attain long-term career goals (i.e., the distal factor of career success was tied to a high grade point average [GPA]). Nonetheless, McKeachie also recognized the power of proximal factors in motivation. He knew that instructors could inspire and motivate, or they could arouse anxiety and uncertainty, undermining student motivation by doing so. McKeachie contended that students analyze the academic tasks they face and make decisions about what and how to study based on the likelihoods of success and the value of the various tasks to them. In short, McKeachie advanced the hypothesis that many other factors than grades play an interactive role in college student academic motivation.

It is important to note, however, we do not imply that Becker et al. (1968, 1995) failed to recognize that there were a variety of factors affecting academic motivation (e.g., extracurricular involvement, the nature of friendships); rather these factors were only covered in passing in their model, with no explanation of just how extracurricular activities and other persons might both encourage and undermine academic motivation. One reason for this was that the participant observation method used by Becker et al. (1968, 1995) involved observation rather than interviewing of students as a central methodology. That is, although questions were posed to participants about the meanings of their behaviors, these seemed not to be as important in driving the conclusions presented in the study as were the observations. Moreover, we infer, based on the salience of the grade point perspective conclusion in the Becker et al. (1968, 1995) write-ups, that this idea emerged as a tentative conclusion early in the study and once identified became a focus of the study (i.e., the investigators were actively attempting to find support for the grade point perspective and were less concerned with elucidating other points that might be made about the undergraduate experience). This suggests that although there was some acknowledgment by Becker et al. (1968, 1995) of multiple factors affecting student motivation, these researchers did not attempt to model completely the motivational world of college students.

In summary, many accounts of academic motivation have focused on specific factors that can influence academic motivation. In general, a number of individual factors have proven to be potent in affecting student academic effort. The real complexity of student motivation, however, cannot come through in investigations that are so limited, for such studies are not intended to be informative about all of the factors affecting or potentially affecting student motivation, but rather they are intended to make the case for the particular influences that are the focus of the investigation. As a result, studies of academic motivation have often considered thin slices of student life rather than attempt to grasp the whole. To study motivation holistically, an inductive, qualitative research approach should be adopted in contrast to the deductive, quantitative approaches typically employed in contemporary studies on motivation.

### *Inductive–Qualitative Research and the Study of College Student Motivation*

In inductive, qualitative research, the researchers do not come to the study with a strong hypothesis but instead intend to induce regularities from participants' perspective. In relation to investigating student academic motivation, the researchers' goal is to identify factors operating in the college environment that might affect academic behavior, rather than to measure factors exactly. The goal is much more to develop a theory, which is very much grounded in data, than to test one (Dey, 2004). The idea was, then, to develop a credible theory of a phenomenon. It is credible because it is based on thorough analyses of data and can be tested in subsequent deductive, quantitative studies. Underpinned by these perspectives and aims, some researchers (e.g., Pressley, Van Etten, Yokoi, Freebern, & Van Meter, 1998; Van Etten, Pressley, Freebern, & Echevarria, 1998) have employed an inductive, qualitative approach in their attempt to capture the full range of variables potentially affecting academic motivation in college stu-

dents. As a first step in that process, these researchers carried out an inductive, qualitative inquiry of academic motivation among college freshmen. The exact method in that study was ethnographic interviewing (Mishler, 1986; Spradley, 1979), with the data analyzed using the method of constant comparison (Strauss & Corbin, 1990, 1997). This recursive process of question generation and response analysis continued until no information gaps were apparent and no novel claims were emerging from the student reports.

More specifically, in Van Etten et al.'s (1998) study, the college freshmen who were the first-round participants responded to the following open-ended questions, with the responses to these questions categorized and related to one another as the beginnings of a grounded theory of freshmen motivation: (a) What is academic motivation? (b) What can enhance or undermine your academic motivation? and (c) Is there anything you would like to add or clarify? After analyzing all participant responses to these questions, the researchers found many information gaps or misconceptions in the emergent theory. As such, new questions (still open-ended but a little more focused) were devised in an attempt to resolve these incongruities. The questions asked in this second round of interviewing included the following: (a) Who or what can enhance or undermine your academic motivation? (b) How can environments affect your academic motivation? (c) What academic activities affect your academic motivation? (d) What non-academic activities affect your academic motivation? (e) How can assignments affect your academic motivation? (f) How can courses or course scheduling affect your academic motivation? (g) How do goals affect your academic motivation? and (h) Are there any additional variables that we have not discussed today, variables that affect your academic motivation? In this study, it took five rounds of questioning by Van Etten and his associates before no new information was entering their model. Table 1 summarizes the major conclusions about freshmen academic motivation that emerged from that study.

*The Present Study*

Building on the past studies reviewed above (Pressley et al., 1998; Van Etten et al., 1998), using an ethnographic interview for data gathering, in the present study we aimed (a) to identify a range of variables/factors, both internal and external to the individual students, that potentially play an influential role in college seniors' academic motivation, (b) to elucidate how these factors may enhance or undermine their motivation, and (c) to build a conceptual model depicting how these potential variables/factors may interact and affect college seniors' motivation in their academic lives. College seniors were the focus in this study for two reasons. First, in relation to the increasing number of dropouts among undergraduate in their senior year of college, the study intended to contribute to the effort of reducing dropouts by providing comprehensive information about the factors that can and do affect motivation at college. Second, complementary to the previous studies of the motivational variables of college freshmen (Pressley et al., 1998; Van Etten et al., 1998), we expected this study to be part of our bid toward the understanding of academic motivation of college students in general. Once factors affecting the freshmen's and seniors' academic motivation are identified, intervention programs developed by the university and stakeholders can then be tailored to the needs of these two distinct groups of students. In our approach to this study, we are aware of and acknowledge the relevance and utility of the many contemporary motivational theories that have been empirically tested, including those major ones mentioned in the beginning of this article (e.g., academic goal orientation theory, attribution theory, expectancy-value theory, future goal perspective, self-worth theory) and that have contributed to researchers' understanding of motivation at all levels. In contrast, and in order to prevent a theoretically biased approach and analysis, we did not begin our investigation with such preconceived motivational constructs theorized in the literature (Dey, 2004). Instead we attempted to be open to all variables/factors potentially affecting academic motivation of the college seniors. In our discussion, however, we will look at and discuss our findings

Table 1  
*Highlights of Freshmen Students' Claims About Academic Motivation*

Motivating factor	Explanation or definition
Good grades	Getting good grades and avoiding bad grades are primary academic motivations.
Other goals in attending college	Getting a good job, independence from family, wanting to meet new people and have fun, and avoiding the real world.
Effort matters	College students are primarily effort theorists, believing effort is key to success.
Personal characteristics of motivated students	They take personal responsibility, feel in control, are organized, monitor progress toward goals, and are not overly anxious. They are good at resisting distractions.
Instructors	Some professors are more motivating than others (e.g., they are interpersonally competent, consistent in their grading, democratic).
Friends and classmates who motivate academic effort	They are enthused about academics and encourage studying.
Family	Families are motivating when they provide encouragement, have realistic expectations, help the student to establish goals, and are confident about academic issues.
Assignments	Challenging but manageable assignments are motivating, as is choice in assignments. Deadlines motivate effort.
Rewards and feedback	Detailed feedback informs and motivates.
General social milieu of the classroom and college	College environments can be generally scholarly, promote responsibility, and provide support, which increases student motivation. In general, smaller classes are more motivating than larger classes.
Physical environment	Environments that motivate studying are well lit, generally quiet, and comfortable.

in light of existing theoretical perspectives of motivation. By doing so, we hope to identify and distinguish between motivational factors/variables that have been explored and documented in the literature and those that have not been widely studied.

### Method

Since the goal of this project was to continue previous studies of undergraduate academic motivation and to map out the full array of college seniors' understandings about academic motivation, we opted for an inductive, qualitative method—the grounded theory approach used in the study of freshmen motivation (see, e.g., Van Etten et al., 1998).

### Participants

The 91 college seniors participating in this study attended an admissions-competitive public university in the northeastern United States. A college senior was defined as having 90 or more college credits and enrolled in a 4-year, degree-granting undergraduate program.

There were four phases of data collection and analyses. The first three phases involved small group interviews that required students to respond to open-ended questions. There were 18 students interviewed during Phase 1, 27 students interviewed during Phase 2, and 29 students interviewed during Phase 3. The Phases 1–3 seniors included 44 women and 30 men ranging from 20 to 36 years of age, with 61 participants ranging from 20 to 23 years of age, and the remaining 13 participants ranging from 24 to 36 years of age. There were 58 Caucasian students, 7 African American students, 5 Latino students, 2 Native American students, and 2 Asian students. Twenty-one students had between 90 and 99 credits, 33 had between 100 and 109 credits, 19 had between 110 and 120 credits, and 1 student had 135 credits. Their college GPAs ranged from 2.14 to 3.92 on a 4-point scale, with 38 students having GPAs between 2.14 and 2.99, and the remaining 36 having GPAs between 3.0 and 3.92. The Phases 1–3 students declared 19 different majors. Thus, the students participating in Phases 1–3 were diverse according to several distinguishing characteristics.

The 17 Phase 4 participants served as a member check for the emergent model (Lincoln & Guba, 1985). There were 14 Caucasian students, 2 African American students, and 1 Asian student. Each had between 90 and 120 college credits, with GPAs ranging from 1.92 to 4.00. These students represented 11 different majors.

### Data Collection, Analyses, and Preliminary Results

Two researchers collected and analyzed all data. There were three interview phases that involved a recursive process of data collection and data analysis, with the results from each phase informing the generation of subsequent interview questions (Lincoln & Guba, 1985; Strauss & Corbin, 1990). Both researchers agreed a priori that phases of data collection would continue until no new information was emerging. Three phases of data collection were necessary to meet this criterion.

*Phases 1–3 data collection and analysis.* All participants were interviewed by two researchers in a quiet room. There were four groups of students interviewed during Phase 1, with 3, 5, 6, and 4 students representing each group. Phase 2 involved interviewing

six groups of students, with 7, 5, 3, 3, 6, and 3 students per respective group. Phase 3 included five groups, with 6, 8, 4, 4, and 7 students per group.

Initially, the two researchers introduced themselves to students, thanked them for participating, and then collected consent and demographic information. All interviews were tape-recorded to allow researchers to clarify notes. At this point, students were informed about the purpose of the research. The initial introduction was as follows,

We are conducting research to identify the variables affecting college seniors' academic motivation. We will ask you several questions. Some of these questions may seem to have common sense answers, but since we do not want to lead your answers, we request that you provide answers with fine details and examples if possible. If you disagree with, or wish to add to another student's response, please feel free to jump into the conversation. We are tape recording this interview so that we can clarify and elaborate on our notes. Please answer openly and honestly. Everything you tell us is completely confidential.

After ensuring that all participants understood the nature of the research, we were ready to ask our first questions. These first questions were very general, intended to elicit a broad array of students' responses that reflect their construal of academic motivation (see Appendix A for the lists of questions asked in Phase 1). Two interviewers were present and took notes summarizing students' responses for each of the four Phase 1 group interviews. Immediately after the first group interview, both interviewers separately analyzed their notes into clauses; these clauses were then synthesized into categories or themes and subcategories. After the first round of coding, to ensure that both interviewers were coding at a comparable level of detail, they exchanged and compared notes. Subsequently, three additional groups were interviewed, with both interviewers agreeing that no new information was emerging at the end of the fourth group interview. The two interviewers again compared categories and subcategories, with clear agreement that at least 14 themes emerged (e.g., goals affecting motivation, feedback affecting motivation, self-characteristics affecting motivation, external factors affecting motivation). Although one of the interviewers coded more clausal statements (i.e., 327 claims) than the second interviewer (i.e., 90 claims), there was clear agreement that comparable results were collected (i.e., the interviewer coding 327 statements recorded very specific claims while the interviewer coding 90 statements tended to make more general claims; thus, most of the 327 claims could be subsumed under the 90 general claims).

At the end of the fourth group interview, there were still many information gaps and emergent information requiring semantic clarification. These concerns were addressed by generating a new set of questions, still open-ended, albeit a bit more focused (see Appendix B for the Phase 2 questions). The only procedural difference between Phase 1 and Phase 2 was that during Phase 2, interviewers followed up less-than-complete student responses with requests for additional information. For example, when a student stated that "Sports really affect my motivation," the researcher asked the student, "How do sports really affect your motivation?"

After each interview, both researchers again coded information into clausal form, with these clauses then related to the preliminary

categories and subcategories emerging from Phase 1 analyses. As new information was collected, tentative categories and subcategories began to merge and/or become reclassified. For example, although feedback as a motivator emerged as a category during Phase 1 coding, it was found to be only a subcategory during Phase 2 coding. That is, during Phase 2, themes such as rewards, grades, and feedback all became subcategories under the main category information about performance.

In contrast to Phase 1 coding, Phase 2 codes had fewer information gaps, and the two interviewers had fewer disagreements requiring resolution. The model was much closer to saturation at this point. Still, there were several issues that required deeper probing. These issues were resolved by generating a third phase of questions, with these questions much more focused than the questions posed in Phases 1 or 2 (see Appendix C for the Phase 3 questions). At the end of the third phase of data collection and analysis, both interviewers agreed that all information gaps and/or misconceptions were resolved. The model was now considered grounded or saturated (see Strauss & Corbin, 1990, 1997), with both interviewers in agreement about the main categories reported by the students and summarized in the Results section of this article.

*Phase 4 data collection and analysis (member checking phase).* Phase 4 involved having 17 students analyze an integrated, comprehensive copy of the claims emerging from Phases 1–3. The purpose of this member check was to ensure that the phenomenology of students' responses was maintained in written form; in addition, this check served to validate the comprehensiveness of the model. The final coded product was 44 double-spaced pages long, with students requested to read and evaluate out loud the accuracy of each claim. In addition, students were requested to write written responses indicating reasons for agreement or disagreement with claims. All student comments served to support the emergent model, including the maintenance of students' interpretations. That is, all of the claims of the emergent model were accepted as correct by these 17 participants.

## Results

### *College Seniors' Model of Academic Motivation*

The seniors reported that there were many variables that can and do affect their academic motivation. The seniors spoke about how the goals of graduating and earning good grades became their primary target goals during their senior year. These goals are distal in nature and inherently future time oriented. Although not entirely mutually exclusive, there were a few large categories of more proximal variables affecting motivation, which can be summarized into two major categories: internal and external factors. Among the internal attributes were students' characteristics (e.g., expectations about themselves, health, past successes and failures, social class) and students' thinking (e.g., beliefs about control, beliefs about whether they are learning much in a course, expectations about courses). The students also cited the influence of a number of factors external to themselves in determining their academic motivation. These included course and assignment characteristics, the nature of examinations and assessments, feedback, rewards, people (i.e., instructors, family members, peers), the college environment (e.g., academic associations, internships and volunteer opportunities, physical characteristics of the environment), and extracurricular participation. Table 2 provides a detailed summary of all of

the individual, conceptually distinct claims made by college seniors about their academic motivation. It is important to state here that the purpose of this research was not to take a tally count of how many times particular themes were mentioned by participants but rather to ensure that the broad sweep of potential motivational influences was given the opportunity to be voiced. This is in line with the agreement by qualitative research methodologists that, depending on the purpose of the study, the outcomes of the ethnographic focus group interview are not necessarily to be quantified (see, e.g., Stewart & Shamdasani, 1998; Wilkinson, 2004). As noted earlier, the primary purpose of this grounded theory study was to generate hypotheses (rather than to test hypotheses) or to address the questions of "what" and "how" or "what is going on" of the college seniors' academic motivation (rather than the issues of "how often" or "how many"). Thus, while we loosely indicate salient motivational influences by comments such as "some students said," this was not based on a precise numerical count. Issues that were occasionally or rarely mentioned were still to be encompassed in our evolving framework. In essence, all claims were given equal weight to generate as rich a data source as possible from which future research may generate hypotheses about student engagement at college. Since visual representations are useful analytical tools in ethnographic research, in particular, to crystallize and chart the consolidated information and to display its line operations (Fetterman, 1998), all of the motivational factors/variables we found and their flow in affecting college seniors' academic motivation are depicted in Figure 1.

### *Academic Goals of Getting Good Grades and Completing the Degree*

As has been true in all previous analyses of college students' academic motivation (e.g., Becker et al., 1968, 1995; Horowitz, 1987), getting good grades was reported as one of the critical determinants or primary target goals of their academic efforts (see Figure 1). The seniors reported that little active processing of academic material would occur without grades. If there were no grades, the seniors reported that they probably would not even attend class. Further, the seniors reported that grades were more motivating if they mattered. For example, there would be greater concern with grades among students expecting to apply to graduate school. The seniors also reported that they were particularly more motivated when graded for personal improvement rather than in competition with other students.

However, a number of situations were noted as undermining the seniors' academic motivation. These included the situations in which the courses they took were too difficult and thus provided little chance to be competitive for the top grades, or in contrast, if students perceived that they were in a course in which all students received high grades. The seniors also stated that their motivation was undermined if they had low-grade expectations and were willing to settle for low or mediocre grades.

Beyond individual grades, however, completing the degree was much on the minds of the seniors, with them offering a variety of reasons or perspectives on how degree completion can affect motivation (see Figure 1). The seniors believed that, in the senior year, most of the hurdles have been surmounted (i.e., most of the

(text continues on page 820)

Table 2

*Summary of College Seniors' Claims About Their Academic Motivation*

College seniors' main goals affecting motivation	
■ <i>How grades and grading policies affect academic motivation:</i>	■ Seniors believe that little active processing of academic material would occur without grades. If there were no grades, they probably would not even attend class.
	<ul style="list-style-type: none"> <li>• Seniors perceive that grades were more motivating if they matter (e.g., to apply to graduate school).</li> <li>• If seniors perceive that they are in a course in which all students receive high grades, there is less academic motivation.</li> <li>• Seniors feel that they are more motivated when graded for personal improvement rather than in competition with other students.</li> <li>• Seniors perceive that in some courses there is little chance to be competitive for the top grades, and this undermines academic motivation.</li> <li>• Some seniors have low grade expectations and are willing to settle for low grades, and this undermines academic motivation.</li> </ul>
■ <i>How completing degree affect academic motivation:</i>	■ Seniors feel that in senior year most of the course-work is completed. Thus, there is no reason to stop when they are so close.
	<ul style="list-style-type: none"> <li>■ All that remains to be completed are electives, allowing students to select courses that are personally interesting or applicable to future occupations.</li> <li>■ Relative to previous coursework, seniors' coursework is often taught from a more applied perspective, not only emphasizing the utility of the material but also hands-on experience (e.g., field placements), and this enhances their motivation.</li> <li>■ Seniors believe that they can complete with minimal time and effort invested, (i.e., they are comfortable at this point in their degree program in missing classes and believe they can superficially process many assignments without much in the way of consequences).</li> <li>■ Seniors believe that if they did not complete, they would have wasted resources (i.e., their parents' money, their time and effort).</li> <li>■ Seniors believe that completing the four-year degree will result in a better job and great earnings in the future, the approval of others, and will be personally satisfying.</li> </ul>
College seniors' internal factors affecting motivation	
Student characteristics	
■ <i>Student characteristics that can positively affect motivation:</i>	<ul style="list-style-type: none"> <li>• Having high expectations and/or goals.</li> <li>• Paying for their own education or having parents pay for education.</li> <li>• Good health.</li> <li>• Feeling successful.</li> <li>• Feeling that they have been recognized for past accomplishment.</li> </ul>
	■ <i>Student characteristics that can negatively affect motivation:</i>
■ <i>Student social class:</i>	<ul style="list-style-type: none"> <li>■ Having goals or expectations that are either very easy or impossible to attain.</li> <li>■ Poor health.</li> <li>■ Wanting to start paying off debts or to have some spending money, resulting in seeking employment or more employment.</li> <li>■ Receiving more recognition for nonacademic pursuits than academic pursuits</li> </ul>
	<ul style="list-style-type: none"> <li>■ Students from lower class backgrounds experience people and institutions (e.g., churches, businesses, drug houses) that can either support or undermine academic motivation.</li> <li>• Students from middle-class backgrounds receive the message that they are "expected to get a college degree" to make a difference in their lives.</li> <li>■ Students from upper-class backgrounds believe that their parents send the message to their children that it is important to get a college degree in order to be perceived as able, that they can make it on their talents.</li> </ul>
Student metacognition	
■ <i>Student beliefs about control:</i>	■ Seniors are more motivated when they believe that have choices in their academic work
	■ <i>Student beliefs about whether they are learning in courses:</i>
■ <i>Expectations about courses and instructors:</i>	■ Motivation is higher when students perceive they are learning something in their courses.
	<ul style="list-style-type: none"> <li>■ Seniors select certain instructors who are more favorable than others in terms of the amount of work they assign, the quality of the work they require, grading policies, instructional approach, and personal qualities, etc.</li> <li>■ Seniors know that certain types of material demand much effort to learn, master, or to get a "good" grade, while other material requires little effort. The expectations about material difficulty can affect whether students take a course.</li> </ul>
■ <i>Student academic planning:</i>	■ Seniors believe that having plans increases academic engagement, recognizing explicitly that academic demands must be addressed during certain times throughout the day or week.
	<ul style="list-style-type: none"> <li>■ A good syllabus in a course is key to student planning. When an informative syllabus is available and stuck with from the beginning of the course, it allows students to gauge the amount of effort and time they will need to complete the course requirements.</li> </ul>
■ <i>Student beliefs about effort, strategy, and ability tradeoffs:</i>	■ While seniors recognize that ability can affect academic performance, they also believe that with effort and efficient strategies, most college students can do well. This belief about "effort-strategy-ability tradeoffs" enhances their motivation.

(table continues)

Table 2 (continued)

## College seniors' external factors affecting motivation

## Academic factors

■ *Course characteristics:*

- Larger class sizes decrease seniors' academic motivation because there is less personal responsibility, classes can be missed without penalty, etc. In contrast, smaller class sizes promote academic motivation because there are more interactions between students and instructors, there is more autonomy, etc.
- Working in large groups often result in students not participating because speaking in front of large groups is difficult for some students. Conversely, smaller groups often are motivating because they feel less threatened.
- When there is group work in a course, it is much more motivating when the students select themselves into groups compared to when instructors assign group members.
- When there is group work in a course, it is much more motivating when all group members complete allocated duties. If some group members fail to complete duties, other group members begin to get worried or disgruntled.
- Study groups can enhance or undermine academic motivation. When all group members are prepared and interested in learning the material, motivation is enhanced. In contrast, when study group members are ill-prepared and not interested in learning the material, motivation is undermined.
- If study group members consist of friends, motivation is often increased, but only if the friends are motivated to learn. However, if study group members do not know one another before studying together, motivation can be enhanced because demands made on members are more often egalitarian.
- Competition in a course can either enhance or undermine motivation. If the competition is against realistic standards (e.g., a "B" student competing against another "B" student, not a "C" student competing against an "A" student), motivation is enhanced. In contrast, when competition sets one up for failure (i.e., it involves competition with much more able students), motivation can be undermined.
- There is greater motivation to do well in courses in the student's major.
- A syllabus that makes the requirements in the course seem overwhelming can undermine motivation.
- Seniors' motivation is low for reading of texts and articles that cannot be understood easily.
- If material in a course is covered in previous courses, there often is little motivation to engage the material again, unless the instructor makes clear the utility and/or applicability of the material in this course.

■ *Assignment characteristics:*

- Seniors are most motivated to do assignments permitting them to apply what they have been learning to a "real" situation.
- Seniors feel that they are motivated to do assignments when they perceive that the material is useful and interesting.
- Choice with respect to assignments increases motivation, although there should not be so many choices that the selection seems overwhelming.
- If the deadline is in the distant future, there is little motivation to do the assignment.
- When large assignments are broken into subtasks distributed across the term (i.e., each subtask has a due date), there is greater motivation than when the large assignment is on one date near the end of the term.
- The difficulty, breadth, and depth of assignments affect student motivation.
- Firm, clear deadlines motivate students to meet those deadlines, whereas the possibility of an extension motivates procrastination.

■ *Examinations and assessments:*

- Seniors recognize that without exams and accountability, much of academic engagement would evaporate. They would read fewer assignments, listen less in class, take fewer notes, and process material less completely.
- Take-home exams can undermine academic motivation when they permit "cheating."
- Some seniors are motivated by take-home exams, believing that take-home exams better capture students' true knowledge than do in-class exams.
- When exams involve group work, there are a variety of potential motivational implications. Motivation can be affected depending on whether there are checks to make certain that all group members contribute to the group product.
- Multiple-choice formats often decrease motivation for seniors because they perceive these formats do not capture student knowledge, which reduces motivation.
- Essay exams motivate seniors in that they allow students to explain themselves. On the other hand, essay exams undermine academic engagement in that students know that often they can write quite a bit even if they know very little, with it easy to skirt around difficult issues in essay responses.
- Graded oral presentations tend to motivate engagement since students believe such presentations are not likely to be received well unless the student is well prepared.
- If a number of exams are occurring at the same time, seniors know to juggle their studying, that is, they know to study less that which is well known and to study more that which is unknown but could be learned given the amount of time available.
- Pop quizzes force students to keep-up with material, but seniors perceive that they cause dislike of the instructor and can undermine motivation or interest toward the course and material.
- It is motivating when professors use exams to diagnose areas of student weakness and then provide opportunities to remediate the weakness.

■ *Feedback:*

- Seniors perceive that positive informational feedback (e.g., this is a good answer because. . .) is the most motivating for them. This type of feedback lets them know that they are doing good work and why.
- Positive evaluative feedback does not have to be informative, however (e.g., good job, correct, good answer), and such feedback is not very helpful.
- If positive informational feedback cannot be given, seniors perceive that the next most motivating type of feedback is negative informational feedback (e.g., this is wrong because. . .). This type of information allows students to correct weaknesses.
- Negative evaluative feedback (e.g. wrong, incorrect, weak) is believed to be least motivating. This type of uninformative feedback often causes students to exert less effort and/or to give-up.

■ *Rewards:*

- Seniors feel that rewards, aside from grades and feedback, can affect their motivation.
- Seniors self-reward themselves when they complete a task, and this enhances their motivation.

Table 2 (continued)

## Social factors

■ *Instructors:*

- Seniors recognize that some instructors are more motivating than others. Some of the following characteristics are shown by the motivating instructors: provide finely-detailed course requirements; relate assignments to course goals; identify critical information for students; present well-prepared lectures; treat all students like adults.

■ *Family members:*

- Family members can enhance seniors' academic coping by providing genuine concern, encouragement, and by helping students establish realistic goals and expectations. In contrast, family members can undermine seniors' academic coping by applying pressure for success, making demands, and by setting unrealistic goals and expectations.

■ *Peers*

- Peers can support academic coping by encouraging studying, by offering an open-minded ear for catharsis, and by being generally academic-oriented. In contrast, peers can undermine academic coping by pressing students to avoid studying and by not providing a source for discussion of academic issues.

## General college environment

■ *Academic associations:*

- Seniors believe that honor societies (e.g., Psi Chi), student councils, and domain-specific associations and clubs (e.g., American Marketing Association, Greek club) stimulate important academic-related learning by providing forums for academic discussions and social networks, that is, they provide students with a way to acquire important academic information.
- One problem with these associations is that for students to be "really accepted" as members, they must devote a lot of personal time (e.g., there is a lot of paper work, scheduling meetings, fund raising events, and other group functions), reducing time for formal academic requirements.

■ *Internships and volunteer opportunities:*

- Seniors think that internship and voluntary activities can enhance students' academic motivation because these activities show why what they are learning is important and is really applicable to their occupation.
- Internships and volunteer opportunities, however, can undermine motivation because these activities require a lot of time, decrease time available for formal academic work, etc.

■ *Physical environment:*

- Seniors perceive that classroom noise, lighting, temperature, cleanliness, and general comfort can affect academic motivation.
- Seniors perceive that motivation can be undermined when a class is in a large classroom as it makes it more difficult for students to see and hear instructors and/or material.
- The weather may affect motivation to attend class, with either beautiful or terrible weather having the potential to reduce motivation to make it to class.
- The distance between home and campus may undermine motivation to attend class.

## Extracurricular activities

■ *Sports:*

- Sports participation can motivate academic activity because most formal college sports require students to maintain certain grade-point-averages and have mandatory study times for lower-achieving students. However, if students become overly devoted to the sport(s), spending a lot of time participating in- or thinking about them, academic motivation can be undermined.

■ *Fraternities and sororities:*

- Fraternities and sororities can motivate academic motivation by requiring participants to maintain certain grade-point-averages, providing a network of individuals knowledgeable about how to do well in college, and having academic competitions within and between fraternities and sororities. Conversely, they can also decrease academic motivation by demanding much time from participants.
- Seniors believe that part-time jobs potentially undermine academic motivation, especially when the job demands much of the students' time.

## College seniors' reasons for working hard, slacking off, and drop out

■ *Reasons for working hard during senior year:*

- Some seniors believe that they always want to do well, and thus, they are continuing to work hard in their remaining coursework.
- Some seniors have experienced a great deal of academic success in college, and this motivates effort during the senior year.
- Seniors, more than other students, are able to select courses that are personally interesting or relevant to future occupational careers, and courses that fit into personal schedules.
- Some seniors perceive that they are really beginning to learn the worth of academic material (e.g., through internships, placements).
- When seniors are still seeking letters of recommendation or believe that remaining courses may affect their acceptance into graduate or professional school, they would exert great effort in the courses that remain.
- By senior year, some students come to the realization that they have had their fun during college (perhaps with some cost in terms of academic achievement), and thus, it is time to really put the effort into academics.
- Some are willing to sacrifice social activities now in favor of academic pursuits, believing that doing well academically now will provide social opportunities for the remainder of their lives.

(table continues)

Table 2 (continued)

- 
- *Reasons for slacking off during senior year:*
    - When seniors already have applied for or been accepted into a graduate or professional training program, academic motivation often decreases because seniors believe that remaining coursework will not affect the decision.
    - If they have already landed a job that will be waiting for them after graduation, there is a similar negative effect on motivation.
    - They believe that the few courses that remain will not much affect overall grade point average.
    - If there are required courses in general education that remain, these seem to be especially unappealing to seniors.
    - Some seniors have experienced a great deal of academic failure in college, and this motivates lack of effort during the senior year. The more failure has occurred following great effort, the less incentive reported to work hard.
    - Seniors invest efforts in keeping the friends they have made. They realize that college will be coming to an end soon and are concerned at solidifying relationships so as to remain in contact with the friends they have made.
    - By senior year, students have developed non-academic interests, (e.g., drawing, shopping, playing with computers, sports).
  - *Motivations to drop out of school (i.e., to not complete the degree):*
    - Some seniors have a history of never achieving academic goals, and thus, they do not expect to complete the degree.
    - Some have fallen so far behind in the specific requirements they need to complete, they perceive there is no hope. Thus, seniors may opt to drop-out rather than spend the overwhelming amount of time and effort that would be required to succeed in advanced courses.
    - Seniors can experience personal emergencies (e.g., injury or serious illness; needing to take care of a sick family member; the death of a close friend or relative).
    - Seniors learn that a college degree will not always secure them a better job (i.e., a better paying job and/or a personally satisfying job).
    - Sometimes seniors learn that a student with 90 or more college credits can often secure the same job as a student with a four-year degree. Seniors reported sometimes being offered jobs requiring them to start immediately.
    - Accepting a job offer before completing a degree permits them to get in better shape financially (e.g., in paying off loans). Students can feel pressed to secure a full-time paying job after having lived off of parents, student loans, and part-time incomes.
    - Seniors want to start living in the "real world." They want to secure the 9-to-5 job that does not require work to be brought home (as compared to college).
    - Seniors want to start applying the information learned over the past 3+ years. They also believe that they will not learn anything new in the last few courses.
    - Seniors perceive that what they lack is experience for the jobs they desire. They perceive that such experience can be gained without having the degree completed.
    - Seniors believe they can complete their degree on a part-time basis while working.
- 

course work is completed). Thus, there was no reason to stop when they were so close. As one senior claimed, "Now it's just a matter of time, or should I say an accumulation of credits?" They felt that if they did not complete, they would have wasted resources (i.e., their parents' money, their time and effort). In relation to the senior year's courses, the seniors espoused that all that remained to be completed were electives, allowing them to select courses that were personally interesting or applicable to future occupations. Further, they stated that, relative to previous coursework, seniors' course work was often taught from a more applied perspective, not only emphasizing the utility of the material but also hands-on experience (e.g., field placements). Thus, seniors believed they could experience a sense of professionalism as they fulfill the requirements that remained. In relation to the consequences of graduating, the seniors perceived that completing the 4-year degree would result in a better job and greater earnings in the future, the approval of others, and personal satisfaction.

### *Student Internal Factors Affecting Academic Motivation*

The seniors in this study reported that students' personal characteristics and their thinking can affect academic motivation. These variables were grouped into one category called *internal Factors* (see Figure 1). In particular, the seniors made observations about the potential role of social class in affecting student motivation. They reported that students from lower class backgrounds experienced people and institutions (e.g., religious institutions, businesses, drug houses) that can either support or undermine academic motivation. Institutions can have a positive influence by supporting the notion that students need a college degree to "get

out of this place," to "help our own," and to "help yourself." They can also have a negative influence on students by suggesting that they have gone far enough in their education. That is, institutional representatives can send the message that a senior from a lower class status has already met and surpassed everyone's expectations, and the senior will always be lower class to everyone else, so why finish the degree.

The seniors in this study also reported that students from middle-class backgrounds received the message that they were expected to get a college degree. The perception was that middle-class students were told that they can make a difference, and hard work resulting in a college degree was what will provide them with opportunities. The seniors also believed that the upper class parents sent the message to their sons and daughters that it is important to get a college degree. The reasons to do so, however, were perceived to be different than for the other two groups. The degree was not so critical to upper class students, who expected a position to be waiting for them in any case, and thus upper class students were reported to be less academically motivated by future employment possibilities. On the other hand, the students reported that some upper class students were motivated to try hard and do well in order to be perceived as able (i.e., that they can make it on their talents).

Among other student characteristics that were reported to affect the seniors' academic motivation were the goals and/or expectations that students set from themselves, with having high goals or expectations positively increasing motivation, whereas having goals or expectations that either are very easy or impossible to attain negatively affecting motivation; the financial resources of

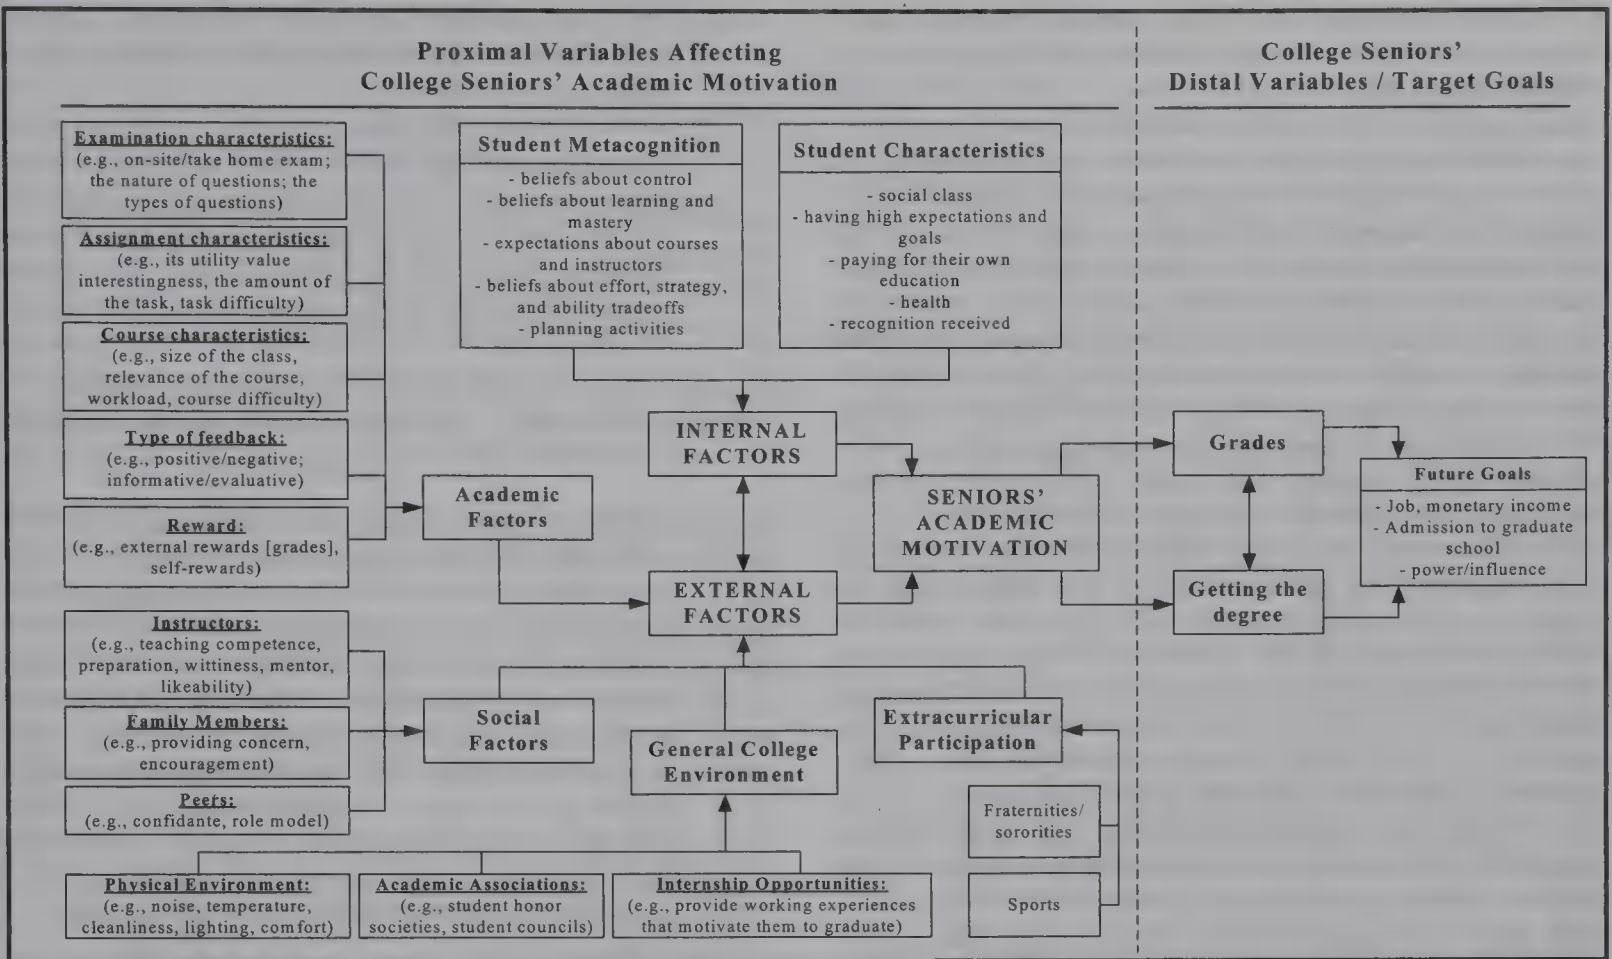

Figure 1. College seniors' model of academic motivation.

their education, with paying for their own education or having parents pay for their education enhancing motivation, whereas wanting to start paying off debts or having some spending money resulting in seeking employment or more employment undermining their academic motivation; health, with good health increasing motivation and poor health decreasing motivation to study; and recognition for past accomplishments, with a feeling or thought that they have been recognized for past accomplishment motivating their academic efforts, whereas receiving more recognition for nonacademic pursuits than academic pursuits potentially demotivating their academic efforts.

The seniors in this study also reported that their thinking was very important in determining academic motivation. This category comprises five different beliefs or thinking process. The first category was student belief about control. The seniors in this study contended that they were more motivated when they believed that they had control or choices in their academic work. The second category was student belief about whether they were learning in courses. Seniors were motivated when they believed that they were learning in their courses. The third category was student expectation about courses and instructors. Based on their experiences in their first three years of college lives, prior to enrolling in courses, seniors often thought about courses and instructors. They have learned that certain instructors are better than others, with instructors evaluated in terms of the amount of work they assign, the quality of the work they require, grading policies, instructional approach, and personal qualities. When possible, seniors attempted to take courses from better instructors, although choice of classes

sometimes was determined by the days and times that classes meet, class size, as well as the number of meeting hours per week. Seniors were also aware that certain types of material demand much effort to learn, to master, or to get a "good" grade in, while other material requires little or less effort. The expectations about material difficulty can affect whether students take a course.

Sometimes students entered classes and confirmed their expectations (i.e., that the instructor was good, the demands were reasonable). At other times, students entered class and expectations were disconfirmed. When expectations were disconfirmed, seniors reported that they often coped with it, for example, by requesting additional time to complete some assignments, handing in work of lower quality, handing assignments in late, or never handing in some assignments. Alternatively, disconfirmation of expectations about teachers and courses can result in a course drop. For example, a student might enroll in a large lecture hall class, expecting minimal personal interaction with the instructor, no attendance policy, and multiple-choice tests. The student has taken this course expecting that it will not be demanding, permitting the student to devote more effort to other courses. If these expectations were not met (e.g., the instructor assigns many group projects that are individually assessed by a teaching assistant), students must adjust their schedules accordingly, the quality of work in their other classes, or drop out of the class. Sometimes dropping out is tempting, rather than risking performance in other courses.

The fourth category was student academic planning. Seniors were active planners before enrolling in classes and throughout the semester. They have learned that in order to succeed in college,

they must plan. Initial planning begins when seniors decided which classes to take, formulating their academic plan in light of other social activities and employment. Seniors created schedules with some flexibility built into them, flexibility allowing them to accommodate for unexpected circumstances (e.g., extra work in a class). They believed that having plans increases academic engagement, recognizing explicitly that academic demands must be addressed during certain times throughout the day or week. Without a fixed routine, students realized that they would be at risk for engaging in anything that comes along when it comes along, often resulting in insufficient time for academics. A good syllabus in a course is key to student planning. When an informative syllabus was available and stuck with from the beginning of the course, it allowed students to gauge the amount of effort and time they would need to complete the course requirements.

The fifth category was student beliefs about effort, strategy, and ability tradeoffs. The seniors recognized that effort exerted and strategies used can affect academic outcomes and that an efficient strategy well matched to task demands can reduce the amount of effort required to carry out an academic task. Although the seniors recognized that ability can affect academic performance, they believed that with effort and efficient strategies, most college students can do well. In particular, they reported that low ability can be offset with efficient strategies and high effort. Still, the seniors were also aware that high effort and/or efficient strategies can still result in repeated failures, with some tasks requiring a great deal of time regardless of efforts and strategies that are used. Even so, in general, the seniors believed that effort and efficient strategies promote success, while little effort and poor strategies typically produce failure.

### *Student External Factors Affecting Academic Motivation*

There are many contextual and social factors affecting student motivation. They are grouped into a first-order category called *external factors* (see Figure 1) and can be divided into four second-order categories: academic factors (course characteristics, assignment characteristics, examination characteristics, feedback, and reward), social factors (instructors, family members, and peers), general college environment (physical environment, academic associations, and internship or volunteer opportunities), and extracurricular participation (fraternities/sororities, sports).

### *Academic Factors*

*Course characteristics.* The seniors reported a number of course-related characteristics that can affect their motivation. These included the following:

1. The size of the class, with larger class size decreasing seniors' academic motivation, and smaller class size promoting their academic motivation. Specifically, seniors perceived that, in large class size, there is less or little personal responsibility. That is, classes can be missed without penalty, and the quality of written assignments can be poor because most often they will be evaluated superficially. Further, in large class size, students can cheat, hand in friends' work, or have friends take tests for them. Large courses usually require only minimal work

(e.g., a midterm and final multiple-choice test). In contrast, the seniors reported that smaller class size promotes academic motivation as there are more interactions between students and instructors, there is usually class discussion requiring students to keep up on the material, there is more autonomy, the evaluation of any assignment is often more detailed in comparison to large class assignments, instructors can account for individual differences and grade for personal improvement, and instructors can assess when a student's work is not consistent with their ability and/or effort. Thus, smaller class size usually requires students to devote more time and effort to academic demands.

2. The size of working groups, with working in large groups potentially undermining academic motivation. Larger groups often result in students not participating because speaking in front of large groups is difficult for some students, they fear being embarrassed in front of peers, and they are never allocated enough time to adequately represent themselves. Conversely, smaller groups often are more motivating, with students reporting that participation increases across the semester. Students reported that this is because they begin to feel more comfortable and less threatened in smaller groups, and they are often allocated sufficient time to fully elaborate responses.
3. The formation of working groups, with student-formed groups more motivating than instructor-formed groups. Further, when there is group work in a course, it is much more motivating when all group members complete allocated duties. If some group members fail to complete duties, other group members begin to get worried or disgruntled.
4. Study groups can enhance or undermine academic motivation. For example, when all group members are prepared and interested in learning the material, motivation is enhanced. In contrast, when study group members are ill prepared or are not interested in learning the material, motivation is often undermined. In addition, if study group members consist of friends, motivation is often increased, but only if the friends are motivated to learn. Even so, if study group members do not know one another before studying together, motivation can be enhanced because demands made on members are more often egalitarian.
5. Type of competition. Competition in a course can either support or undermine motivation. If the competition is against realistic standards (e.g., a B student competing against another B student, not a C student competing against an A student), motivation is enhanced. In contrast, when competition sets one up for failure (i.e., it involves competition with much more able students), motivation can be undermined.
6. There is greater motivation to do well in courses in the student's major.

7. A syllabus that makes the requirements in the course seem overwhelming can undermine motivation.
8. Student motivation is low for reading of texts and articles that cannot be understood easily.
9. If material in a present course was covered in previous courses, there often is little motivation to engage the material again, unless the instructor makes clear the utility and/or applicability of the material in the course.

*Assignment characteristics.* The seniors described a number of assignment-related characteristics that can affect their motivation. These included the following:

1. Applicability value of assignment. Seniors were most motivated to do assignments permitting them to apply what they have been learning to a "real" situation. Seniors believed that they were ready to start applying the definitions, concepts, and theories they were learning. They were ready to start learning about the material in action. For example, they would rather interview people who perform a real-world task than simply read about how to do the task.
2. Utility value of assignment. Seniors reported being motivated to do assignments when they perceived that the material was useful. If assignments or material were perceived to have no utility or no face relevance, motivation was diminished. Seniors reported that they sometimes cheated to complete apparently worthless assignments.
3. Interestingness of assignment. Seniors reported being motivated to do assignments that were perceived as interesting.
4. Difficulty of assignment. The difficulty, breadth, and depth of assignments affected student motivation. Assignments that required too much attention to details or the processing of an overwhelming amount of material were demotivating. If assignments were very difficult (i.e., students have low prior knowledge about the issues, it is unclear what needs to be done to complete the assignment, or the sheer time needed to complete the task would inhibit the completion of other assignments), seniors sometimes sought help. However, regardless of whether they received assistance, they decided either to devote the time necessary to complete the assignment adequately or to devote minimal time and effort to complete the assignment without concern with the quality of the work. What determines how a given student will respond to the difficult assignment? If the student has developed rapport with the instructor or needs something from that instructor (e.g., recommendation), seniors reported being more likely to seek help and attempt to complete the assignment well. Similarly, if the assignment was in their major, or they were very interested in the topic, seniors reported devoting the extra effort. Students reported opting for minimal time and effort when

they did not want to diminish the quality of other assignments they considered more important. However, the seniors also reported that easy assignments did not motivate much effort, unless the student was attempting to impress the instructor or was very interested in the assignment or the material. Easy assignments do not receive much time, unless the time is available. The seniors claimed that the most motivating assignments were challenging but manageable (i.e., with reasonable time and effort, a good quality outcome can be achieved). Instructors can play a key role in conveying to students that assignments are manageable by making clear how the assignment can be accomplished.

5. Availability of choices. Choice with respect to assignments increases motivation, although there should not be so many choices that the selection seems overwhelming.
6. If the deadline is in the distant future, there is little motivation to do the assignment. When large assignments are broken into subtasks distributed across the term (i.e., each subtask has a due date), there is greater motivation than when the large assignment is on one date near the end of the term. The seniors reported that sometimes they broke large assignments into subtasks and set their own deadlines for subtasks in order to increase their motivation for completing the entire task. Further, firm, clear deadlines motivate seniors meeting those deadlines, whereas the possibility of an extension motivates procrastination.

*Examinations characteristics.* The seniors recognized that without exams and accountability, much of academic engagement would evaporate. They would read fewer assignments, listen less in class, take fewer notes, and process material less completely. The following characteristics of examination affect the seniors' academic motivation.

1. Types of questions/tasks in the exam. Seniors reported that multiple-choice formats often decrease motivation for seniors because they perceive that they can usually do well by merely memorizing material. Seniors also perceive that multiple-choice exams often do not capture student knowledge, which reduces motivation. In particular, items that are poorly constructed undermine motivation in that seniors know that some questions can be answered on the basis of structural characteristics of the items rather than requiring knowledge of the course material. In contrast, essay exams motivate students in that they allow students to explain themselves. Nonetheless, essay exams can undermine academic engagement in that students know that often they can write quite a bit even if they know very little, with it easy to skirt around difficult issues in essay responses. Oral presentations that are graded tend to motivate engagement since students believe such presentations are not likely to be received well unless the student is well prepared. Lastly, the seniors reported that far too many exams require only memorization, and this does not motivate academic en-

agement. They perceived exams that require application of what they learn as more motivating but occurring infrequently.

2. Take-home or in-class exams. Seniors believed that take-home exams can undermine academic motivation when they permit cheating. Of course, this negative motivational quality of take-homes can be eliminated (e.g., the exam requires that each student integrates material in a novel way). However, other students are motivated by take-home exams, believing that they better capture students' true knowledge than do in-class exams.
3. Social aspect of exam. When exams involve group work, there are a variety of potential motivational implications. For example, some students like group work more than do other students. Motivation can be affected depending on whether there are checks to make certain that all group members contribute to the group product.
4. The number of simultaneous exams. If a number of exams are occurring at the same time, seniors know to juggle their studying, that is, they know to study less that which is well known and to study more that which is unknown but could be learned given the amount of time available.
5. Aim of exam. Seniors reported that it is motivating when professors use exams to diagnose areas of student weakness and then provide opportunities to remediate the weakness. One way to do so is to permit students to correct incorrect exam answers for some credits.
6. Quizzes. Pop quizzes force students to keep up with material, but the seniors report that they cause dislike of the instructor and can undermine motivation or interest toward the course and material.

*Feedback.* In addition to grades, seniors receive other types of feedback (e.g., verbal feedback about the student's potential for success in the field). With regard to feedback, seniors reported that positive informational feedback (e.g., "This is a good answer because . . .") is the most motivating for them. This type of feedback lets them know that they are doing good work and why. However, positive feedback can simply be evaluative and not informative (e.g., "good job," "correct," "good answer"), and such feedback is not very helpful. If positive informational feedback cannot be given, the seniors reported that the next most motivating type of feedback is negative informational feedback (e.g., "This is wrong because . . ."). This type of information allows students to correct weaknesses. It is not surprising that negative evaluative feedback (e.g., "wrong," "incorrect," "weak") was reported as least motivating. This type of uninformative feedback often causes students to exert less effort and/or to give up.

*Rewards.* Seniors reported that rewards, aside from grades and feedback, can affect their motivation. The students reported that external rewards are rare (e.g., admissions to graduate school, for example, come only to a few and then only at the end of the degree program). In part, because of the lack of external rewards, students self-reward themselves. The seniors reported that for self-rewards

to be effective, self-reward should not occur until the task is complete, self-rewards should be realistic and cost efficient (i.e., students cannot afford to go to the movies every day or buy a new set of clothes each day; thus, self-rewards need to be things such as free time for reading, talking on the phone, or sleeping).

### *Social Factors*

In general, people who are motivating are those who support students' academic engagement, provide strategies for dealing with academic demands, and are willing to listen and help resolve students' personal and academic problems.

*Instructors.* Instructors vary in ways that can affect motivation, with more motivating instructors having the following characteristics and/or practices: They provide finely detailed course requirements; they relate assignments to course goals; they identify critical information for students; they provide old tests and other material to help students review for exams; they test only material covered in the course; they provide adequate time for students to complete assignments and tests; they present well-prepared lectures; they advocate democratic discussion during class; they connect course material to pragmatic issues; they have good elocution skills and speak without an accent; they seem enthusiastic and interested in the material; they are responsible, knowledgeable, and permit choices; they are caring and empathetic to students' personal and academic concerns; they establish realistic but challenging goals; they provide realistic encouragement; they provide timely informational feedback; they grade for personal improvement and emphasize the learning process over grades; they grade based on multiple assessments rather than one big assessment (e.g., instead of one large paper grade, there is grading of subtasks accomplished as the paper is composed); and they treat all students like adults.

*Family members.* The seniors in this study reported that family members can enhance students' academic motivation by providing genuine concern, by providing encouragement, and by helping students establish realistic goals and expectations. In contrast, family members can undermine students' motivation by applying pressure for success, by making demands, and by setting unrealistic goals and expectations.

*Peers.* The seniors in this study also stated that peers can support academic motivation by encouraging studying, by offering an open-minded ear for catharsis, and by being generally academic oriented. In contrast, peers can undermine academic motivation by pressuring students to avoid studying and by not providing a source for discussion of academic issues. The awareness of the role of peers in motivation prompts action by some students, for example, to seek new friends in an attempt to do better academically. Other students, however, reported that they did not seek to control their motivation by affecting the network of people surrounding them.

### *The General College Environment*

Seniors contended that the general college environment can range from promoting responsibility, encouraging effort, and providing support to encouraging dependency, ability, and a lack of support. For example, if faculty, college personnel, and other students in a college or department really attempt to help others

(e.g., by steering them through red tape), this can support academic motivation. Academic environments that are not so supportive require students to do everything for themselves, increasing the likelihood that students will be overwhelmed.

*Academic associations.* The seniors reported that honor societies (e.g., Psi Chi), student councils, and domain-specific associations and clubs (e.g., American Marketing Association, Greek club) stimulate important academic-related learning by providing forums for academic discussions and social networks, that is, they provide students with a way to acquire important academic information. These associations help students build up résumés and locate employment. Sometimes, they also provide help with general (e.g., problems with an instructor) and specific (e.g., seeking information about course material) academic issues. One problem with these associations is that for students to be really accepted as members, they must devote a lot of personal time (e.g., there is a lot of paper work, scheduling meetings, fundraising events, and other group functions), reducing time for formal academic requirements.

*Internships and volunteer opportunities.* Seniors often have internships and/or volunteer. The seniors reported that these activities can enhance students' academic motivation in different ways: They make more obvious why what they are learning is important and is really applicable to their occupation; they provide feedback about whether they can perform the jobs to which they aspire; and they sometimes expose students to opportunities that require post-baccalaureate education, which motivates students to go to graduate or professional school. In contrast, internships and volunteer opportunities can undermine motivation in the following ways: They can demand a lot of time, decreasing time available for formal academic work; they may be too difficult or too easy; the students do not enjoy the applied nature of their field; or the students can learn that they do not have the qualities necessary to fulfill job requirements. In other words, the seniors believed that they learned most and were most motivated by an internship or volunteer opportunity of medium difficulty, one that allows them to learn whether they would prefer such a position in the future but one that does not require so much time that course work would be affected.

*Physical environment.* The students reported that the immediate physical environment has a big impact on whether a student is motivated. The seniors reported that classroom noise, lighting, temperature, cleanliness, and general comfort can affect academic motivation. They reported that motivation can be undermined when a class is in a larger classrooms, which makes it more difficult for students to see and hear instructors and/or material. Further, if the physical environment is filled with people the student knows, it can affect motivation to attend or skip class. For example, if the student is in an environment in which he or she is likely to see friends before class, those friends sometimes provide temptations to skip class. The seniors also reported that weather can affect motivation to attend class, with either beautiful or terrible weather having the potential to reduce motivation to make it to class. And lastly, if a student lives a distance from campus, this can undermine motivation to attend class.

### *Extracurricular Activities*

The seniors in this study also reported that extracurricular activities or participation also have the potential either to enhance or

detract from academic motivation. One of these extracurricular activities is sports participation, which was reported to have a positive effect on the seniors' academic motivation. Most formal college sports require students to maintain certain GPAs and have mandatory study times for lower achieving students. Participation in sports also forces many seniors to structure an otherwise unstructured lifestyle, including scheduling of study. Both formal and informal sports also provide seniors with a break from academics. Seniors perceived that these breaks allow students later to tackle academic demands with renewed vigor. Still, if students become overly devoted to the sport(s), spending a lot of time participating in, or thinking about them, academic motivation can be undermined. Also, sporting events often are scheduled during school hours, which undermines academic motivation by producing the perception that it is acceptable to miss classes and that sports are more important than academics.

Another extracurricular activity reported by the seniors as affecting their academic motivation is fraternities/sororities. The participation in fraternities/sororities can enhance motivation because it requires participants to maintain certain GPAs, providing a network of individuals knowledgeable about how to do well in college and having academic competitions within and between fraternities and sororities. Conversely, they can also decrease academic motivation by demanding much time from participants and providing old tests, papers, and/or other assignments.

### Discussion

Van Etten et al. (1998) made the case that the factors affecting the academic motivation of freshmen were many and complex. In this study, it was clear that the motivational influences on seniors are greater and more complex. For example, college seniors are oriented to two worlds, both the supports and demands of college and the uncertain challenges of the postcollege world (cf., Chickering & Schlossberg, 1998). With respect to the demands and supports of college itself, there was a distinct difference between the seniors and the freshmen we studied previously. Seniors are critically aware that their negotiation of college per se is an end-of-a-venture experience, for example, saliently aware of the competing motivations for completing the degree versus dropping out and for working hard in senior year versus slacking off. The freshmen, of course, were motivated to figure out the challenging, new environment they were confronting.

That seniors have some distinct motivations should not obscure, however, that there also is much overlap in the motivations of the freshmen in Van Etten et al. (1998) and the seniors in this study. For example, both groups of students cited a variety of personal characteristics as important in determining motivation, although again there were many more characteristics cited by the seniors, including a keen awareness that the nature and reasons for academic motivation can vary with social class. Freshmen and seniors also know that student thinking really matters, although again, experience in college permitted much more detailed reports by seniors about how thinking affects motivation than by freshmen (e.g., seniors have detailed expectations about courses based on what they know about instructors and other students' experiences, and they know how they react to violations of their expectations). A related point is that although freshmen knew in general that course, assignment, and instructor characteristics matter, the se-

niors offered detailed observations about how courses, assignments, exams, and instructors can vary in ways that affect motivation. Although freshmen seem to know that the general college environment affected their motivation and could provide detailed information about some aspects of the environment and its effects on motivation (e.g., qualities of the physical environment), the general environment of the seniors is richer and more complex. For example, the seniors have experienced the effects of departments that are helpful to students versus those that are not and know how the department atmosphere can affect motivation. Seniors have also participated in the interactions that occur in clubs, internships, sports, and jobs and know how these aspects of college life can positively and negatively affect academic motivation.

One very salient similarity between freshmen and seniors, and one confirming the perspective development by Becker et al. (1968, 1995), is that grades are important in the thinking of college students. That said, the seniors provided much more information about occasions in college when getting a good grade matters less and when it matters more. Although a good case could be made from the Van Etten et al. (1998) data that getting good grades is the main orientation of freshmen, with seniors, the conclusion has to be adjusted: Getting good grades is often important to seniors, although seniors also know when grades just do not matter that much (e.g., when their graduate school applications and accompanying transcripts are in the mail at midsenior year).

Something that was very intriguing in the senior results, when considered in light of the motivational literature in general, is that the senior students reported in several different ways that neither easy nor overly difficult tasks were motivating. Rather, tasks that are moderately difficult are the most engaging, consistent with theoretical perspectives as diverse as White's (1959) competence model and Vygotsky's (1978) conception of the zone of proximal development (i.e., when tasks are just a bit beyond what the student can do already, students are likely to be most motivated).

One great value of a study such as this one is that it provides so much information to those who serve college students—such as professors and administrators—about what they can do to motivate students and, conversely, the things that can happen in college that undermine student motivation. Indeed, we are struck that this interview study provided much more expansive information than the Van Meter, Yokoi, and Pressley (1994) study about factors that make a difference in facilitating versus undermining students' learning and academic motivation. In that investigation, the focus was on student note taking and the factors affecting it, which was expected to be illuminating since note taking is the principal activity occurring in college class meetings. What becomes clear in this study as well as in Van Etten et al.'s (1998) study is that the factors affecting note taking are just a small subset of the many factors defining student motivation. Motivation is determined by in-class factors and out-of-class factors, by instructor characteristics, but also by the characteristics of many others in the college environment. Consistent with Van Meter et al.'s conclusions, however, what emerges from comparing the freshmen results in Van Etten et al.'s (1998) study and these senior results is that freshmen and seniors are very different, with seniors having highly differentiated and complex conceptions of the college world compared to freshmen. Colleges are complex places, and 4 years of studentship reveal many complexities that are important to students.

An obvious criticism of this study is that it relied on interview data, rather than ethnographic observations. Although there have been few ethnographic observational studies of the college experience, and none that we know of that focus on academic motivation per se, there is reason to believe that when an ethnographic observational study is carried out that focuses on motivation, the results will complement the interview outcomes presented here. For example, in reading anthropologist Michael Moffatt's (1989) *Coming of Age in New Jersey: College and American Culture*, an ethnographic observational study of college life conducted in the late 1970s and early 1980s at Rutgers, we found many bits and pieces of information confirming the big motivational categories detected in this study and in Van Etten et al.'s (1998) study. Notably, however, the extensive detail reported in this study was missing with respect to motivation in Moffatt's report, of course, reflecting that academic motivation was not the central concern in that study. Even so, there is every reason to believe based on Moffatt's study that observation of students will yield information about the importance of grades and long-term goals; information about how and when students exert academic efforts; insights about how professors, dorm mates, and parents affect student course taking and studying; and how the many aspects of the college environment affect academic motivation. Even more optimistically, perhaps with this work providing theoretical sensitivity to the future ethnographic observer, that work will be even more informative than it would be otherwise. The richness of the academic motivations of seniors suggested by the results reported here, and the richness of the academic motivations of freshmen as suggested by Van Etten et al. (1998), provide plenty of motivation for researchers to continue to study the motivations of college students in a more structured manner.

(Appendixes follow)

## Appendix A

## The List of the Phase 1 Questions

1. What is academic motivation?
2. When is your academic motivation affected?
3. Where is your academic motivation affected?
4. Why is your academic motivation affected?

5. How is your academic motivation affected? *Note.* The presentation order of Questions 2–5 was varied for each group, as we felt this would stimulate the maximum variability in responses.

## Appendix B

## The List of the Phase 2 Questions That Were Generated to Clarify Phase 1 Misconceptions and Information Gaps

1. What is enhancing or undermining your motivation to continue in college, and how?
2. What enhances or undermines your motivation to do well or succeed in college, and how?
3. Who enhances or undermines your motivation to do well in college, and how?
4. How can the environment where you learn enhance or undermine your motivation to do well academically?
5. What academic activities can enhance or undermine your motivation to do well academically?

6. What nonacademic activities can enhance or undermine your motivation to do well academically?
7. How can assignments or class material enhance or undermine your motivation to do well academically?
8. Are there any additional variables affecting your academic motivation that we have not discussed today? Are there any other things you would like to add or clarify?

## Appendix C

## The List of the Phase 3 Questions

1. What is boring and/or interesting about being a college senior? Does this affect your academic motivation? How?
2. What is different about being a college senior versus your first three years of college? Does this affect your academic motivation? How?
3. Are there certain activities that college seniors engage in that can affect academic motivation?
4. As seniors, is the material you discuss or how you discuss it affect your academic motivation? Is this different from your first three years?
5. As seniors, what results in superficial or more elaborate processing of academic material?

6. Do some college seniors cheat? What are some of the reasons for cheating as a college senior? How do they cheat?
7. Are there any similarities and/or differences about the “real world” and life as a college senior? How do these similarities or differences affect your academic motivation?
8. What does it take to become a college senior?
9. Do you have anything else you would like to add or clarify, questions that you think we should be asking?

# Dynamic Assessment of Algebraic Learning in Predicting Third Graders' Development of Mathematical Problem Solving

Lynn S. Fuchs, Donald L. Compton, Douglas Fuchs, Kurstin N. Hollenbeck, Caitlin F. Craddock, and  
Carol L. Hamlett  
Vanderbilt University

Dynamic assessment (DA) involves helping students learn a task and indexing responsiveness to that instruction as a measure of learning potential. The purpose of this study was to explore the utility of a DA of algebraic learning in predicting third graders' development of mathematics problem solving. In the fall, 122 third-grade students were assessed on language, nonverbal reasoning, attentive behavior, calculations, word-problem skill, and DA. On the basis of random assignment, students received 16 weeks of validated instruction on word problems or received 16 weeks of conventional instruction on word problems. Then, students were assessed on word-problem measures proximal and distal to instruction. Structural equation measurement models showed that DA measured a distinct dimension of pretreatment ability and that proximal and distal word-problem measures were needed to account for outcome. Structural equation modeling showed that instruction (conventional vs. validated) and pretreatment calculation skills were sufficient to account for math word-problem outcome proximal to instruction; by contrast, language, pretreatment word-problem skill, and DA were needed to forecast learning on word-problem outcomes more distal to instruction. Findings are discussed in terms of responsiveness-to-intervention models for preventing and identifying learning disabilities.

**Keywords:** dynamic assessment, math word problems, responsiveness to intervention

A major purpose of educational assessment is to forecast academic achievement. The goal is early identification of students who are at risk for poor learning outcomes so that intervention can be initiated before the development of severe academic deficits, which can be intractable and can create life-long difficulty in and out of school (e.g., Rivera-Batiz, 1992). The predominant approach for forecasting academic achievement is traditional testing with a general measure of intelligence (e.g., Raven Progressive Matrices; Raven, 1960) or a test of specific ability or skill presumed to underlie future academic performance (e.g., phonological processing for development of word-reading performance or calculations skill for development of mathematics word-problem performance). In these conventional testing situations, examinees respond without examiner assistance, and a body of work demonstrates that assessments of intelligence or precursor abilities/skills capture varying amounts of variance in forecasting academic development. For example, a measure of quantity discrimination, when used as a screener near the beginning of first grade, accounts for 25%–63% of the variance in end-of-year math outcomes

depending on the study (e.g., Chard et al. 2005; Clarke & Shinn, 2004; Lembke & Foegen, 2006).

Because these conventional assessments are imperfect predictors of academic learning (e.g., Sternberg, 1996), they have long been the target of scrutiny and criticism (e.g., Tzuriel & Haywood, 1992). A major concern is that these “static” estimates of performance reveal only two states: unaided success or failure. By contrast, as Vygotsky (1934/1962) proposed, children may function somewhere between these states: unable to perform a task independently but able to succeed with assistance. This has implications for discriminating students at the lower end of the distribution. For example, when two children earn the same low score on a calculations test, they may not have the same potential to develop word-problem skill. One may succeed in learning how to solve word problems given only minimal assistance. This would suggest that the initially low performance on the static assessment stems from inadequate learning opportunity in the child's present environment but indicating good learning potential with competent instruction in the future. The other child may struggle to learn to solve word problems even when provided highly explicit instruction (revealing the need for special intervention).

So the question arises: If the goal is to forecast learning potential, why not assess the student's capacity to learn, rather than assessing what the student presently knows? This alternative form of assessment, whereby students' learning potential is measured, is known as *dynamic assessment* (DA). DA has been the focus of discussions and research for more than 75 years (e.g., Kern, 1930; Penrose, 1934; Rey, 1934, as cited in Grigorenko & Sternberg, 1998). In the present study, we considered the contribution of a DA in forecasting students' development of word-problem com-

petence across third grade. In this introduction, we present a framework for considering prior DA work related to the present study. Then we clarify how the present study builds on and extends this literature.

### Prior Work on DA as a Predictor of Academic Development

DA involves structuring a learning task, providing feedback or instruction to help the student learn the task, and indexing responsiveness to the assisted learning phase as a measure of learning potential. Research on DA varies as a function of the structure and design of the DA and in terms of the methodological features of the studies.

In terms of structure and design, DAs vary along three dimensions (see Campione, 1989): *index*, style of interaction, and the nature of the skills assessed. *Index* refers to the way in which DAs quantify responsiveness to the assisted phase of learning. This is the measure of learning potential. The first strategy for indexing performance is to characterize the amount of change from an unassisted pretest to an unassisted posttest (with the assisted learning phase intervening between the pre- and posttest) or by scoring students' unaided performance following the assisted phase of assessment (e.g., Ferrara, Brown, & Campione, 1986). The second approach for indexing performance is to quantify the amount of scaffolding required during the assisted phase of assessment to reach criterion performance (e.g., Murray, Smith, & Murray, 2000; Spector, 1992). These alternative methods for indexing DA performance serve the same purpose: to predict whether students require extra attention in order to learn adequately. Researchers who use change from unassisted pre- to posttest or use unaided performance following the assisted phase of assessment typically contrast normal learners against special populations of learners (e.g., students with mental retardation) to examine whether the assisted learning experience produces differential learning outcomes as a function of having a diagnosis associated with inadequate learning (e.g., mental retardation). This suggests that low DA scores (less improvement as a function of assisted learning or unaided performance score following assisted learning) serve to predict poor outcomes in other learning situations, indicating that extra instructional support is required to produce adequate learning. In a related way, when research shows that amount of scaffolding predicts learning outcomes outside of DA, this provides evidence that low DA scores (a lot of scaffolding needed to reach criterion performance during the assisted learning phase) serve to predict poor outcomes in other learning situations, indicating that extra instructional support is required to produce adequate learning.

The second dimension along which DA varies is the style of interaction. Some DAs (e.g., Ferrara et al., 1986) are standardized, where the tester administers a fixed series of prompts; success with early prompts reflects the need for minimal adult intervention to perform/learn the task, whereas success on later prompts reflects the need for more extensive adult help to perform/learn the task. By contrast, other DAs (e.g., Tzuriel & Feuerstein, 1992) are individualized, where the tester addresses the student's specific obstacles as revealed by that student's responses.

The third dimension along which DA varies is the nature of the skills assessed. Early work (e.g., Budoff, 1967; Feuerstein, 1979) tended to focus on domain-general skills associated with cognitive ability. In more recent work, tasks tend to be more academically grounded (e.g., Bransford, Delclos, Vye, Burns, & Hasselbring, 1987; Campione, 1989; Campione & Brown, 1987; Spector, 1992).

In terms of research questions and methodological features, some DA studies focus on the amount of learning that accrues on the DA task as a function of student characteristics or the structure of DA (e.g., Tzuriel & Feuerstein, 1992). This approach dominated DA research in the 1970s, 1980s, and 1990s. Alternatively, studies consider DA's contribution in explaining academic performance outside the DA. This second class of studies can be categorized further in terms of two major methodological features. The first is whether studies account for competing predictors of outcome (including static assessments) while considering DA's contribution in predicting academic performance. The second methodological feature is whether academic performance (the outcome) is assessed concurrently with DA (the predictor) or at a later time.

Compared to studies that do not control for competing predictors of outcome, studies that exert such control impose a more stringent falsifiability criterion for considering the value of DA. In terms of the timing of the academic outcome, studies that measure academic performance at a later time enhance external validity, given that the purpose of DA is to forecast future academic achievement. After all, if we were interested in present academic performance, the parsimonious approach would be to measure present achievement directly, not via DA. However, it is also possible that forecasting later academic performance creates variance for DA to capture because the relation between learning potential as indexed via DA and upcoming learning in response to instruction may be stronger than the relation between static assessments (which may be determined by culture, socioeconomics, and previous learning opportunity) and upcoming learning. This empirical issue is, of course, central to questions about DA's utility as a measure of learning potential. For these reasons, in the present study, we examined the contribution of DA in explaining academic performance while accounting for competing predictors of outcome.

To contextualize the present study, we therefore restricted attention in our overview of prior work to the subset of investigations that also explored DA's contribution in predicting academic performance while controlling for competing predictors. We did, however, consider studies that predicted concurrent as well as future academic performance. We also included DAs of varying structure and design. That is, if a study predicted academic outcome while accounting for competing predictors of outcome, we included it regardless of whether the outcome was measured concurrently or in the future, regardless of the way in which DA performance was quantified, regardless of the style of the DA interaction, and regardless of the nature of the DA skills assessed. (For a comprehensive DA review, inclusive of all structures and designs as well as all research questions and methodological features, see Grigorenko & Sternberg, 1998.)

Using our inclusion criteria, we identified three relevant studies.<sup>1</sup> In the first study, Speece, Cooper, and Kibler (1990) measured first-grade students' learning potential with a DA task involving a domain-general skill associated with overall cognitive ability: solving matrices that were borrowed from intelligence tests. Using a standardized style of interaction, the researchers indexed learning potential via the number of prompts required during the assisted phase of assessment. Speece et al. assessed the contribution of DA over verbal IQ, pre-DA matrices performance, and language ability for indicating performance on concurrently administered tests of reading and math achievement. Although statistically significant, DA accounted for less than 2% of the variance in concurrent math performance.

Also predicting concurrent academic performance and using a standardized form of DA, Swanson and Howard (2005) extended the work of Speece et al. (1990) by centering DA on cognitive abilities presumed to underlie reading and math performance: phonological working memory (i.e., rhyming tasks that required recall of acoustically similar words) and semantic working memory (i.e., digit/sentence tasks that required recall of numerical information embedded in short sentences). Four standardized hints were available to DA testers, who selected hints that corresponded to students' errors, choosing the least obvious, relevant hint. Three DA scores were generated: gain score (highest score obtained with assistance), maintenance score (stability of the highest level obtained with assistance probing after assistance was removed), and probe score (number of hints to achieve highest level). The sample comprised students classified as poor readers, skilled readers, reading disabled, or math and reading disabled, with the age of participants averaging 10–12 years. To predict concurrent performance on the Wide Range Achievement Test—Reading and Arithmetic subtests (Wilkinson, 1993), the DA scores for phonological working memory were combined into a factor score; the same was done for DA semantic working memory. The competing predictors were verbal IQ and pre-DA working memory, which were entered first into multiple regression analyses. In predicting reading, pre-DA semantic working memory, verbal IQ, and semantic DA provided unique variance; the unique contribution of the semantic DA factor was 6%. In predicting arithmetic, pre-DA phonological working memory, verbal IQ, and semantic DA provided unique variance; the unique contribution of the semantic DA factor was 25%.

So whereas Speece et al. (1990) found more limited support for DA's added value as related to math performance when DA addressed a domain-general task associated with cognitive ability, Swanson and Howard's (2005) work, which centered DA on cognitive abilities presumed to underlie reading and math performance, was more encouraging. Neither study, however, assessed students' academic performance at a later time. Given that DA's purpose is to forecast future academic achievement, delaying outcome assessment seems important for external validity. In addition, delaying outcome assessment may create variance for DA to capture, as already discussed.

We identified only one study that centered DA on cognitive abilities presumed to underlie reading and math performance (as done by Swanson & Howard, 2005) and, in contrast to Speece et al. (1990) and Swanson and Howard, delayed the assessment of academic achievement to later in the school year. Spector (1992) administered a standardized DA of phonemic awareness, indexing

number of prompts to achieve criterion performance, in November of kindergarten, and then assessed word-level reading skill in May of kindergarten. DA substantially enhanced predictive validity beyond initial verbal ability and beyond initial, static phonological awareness performance in predicting end-of-kindergarten word-reading skill, explaining an additional 21% variance. In fact, November DA was the only significant predictor of May word-reading skill. These results provide promising evidence that DA may enhance the prediction of student learning.

We also considered one additional investigation, even though it did not meet our inclusion criteria (in that it considered DA's relation to post-DA performance on items that mirrored the DA tasks). This study nonetheless helped inform the present study because of its statistical methods. With 84 preschool children, Day, Engelhardt, Maxwell, and Bolig (1997) created DAs that focused on domain-general skills associated with cognitive abilities: similarities and block design tasks. The style of interaction was individualized (i.e., the tester addressed the specific obstacles revealed by the student's responses), and learning potential was indexed by trials to criterion performance. For block design, for example, children were taught a four-step strategy, which the experimenter initially modeled using a four-block problem. If the child failed to solve another four-block problem correctly, more guidance was provided on a three-block problem. Assistance was provided whenever a child failed to solve a problem correctly until he/she solved three consecutive four-block problems without assistance. A transfer task that varied the block design was also presented, with analogous support to learn, and the researchers assessed pre-DA and post-DA similarities and block design performance. Pre-DA performance was considered a competing predictor; post-DA performance was the outcome.

We were interested in Day et al.'s (1997) use of structural equation modeling to test competing measurement and structural models. The measurement model that retained DA as a construct separate from pre-DA and post-DA provided better fit of the data. Thus, DA appeared to tap a construct separate from pre-DA performance, even on analogous tasks. In predicting post-DA scores, Day et al. contrasted four structural models and thereby showed that DA was a viable and necessary predictor of post-DA performance. Of course, academic (or preacademic) performance or learning, which is the relevant outcome to consider when assessing DA's value in predicting achievement, was not considered. Accordingly, Day et al. concluded,

We do not know how dynamic measures related to everyday or school learning or how schooling might affect the relationships among the same measures in children older than those who participated in the present study. . . . Finally, the primary advantage of dynamic measures may lie in how well they predict the ease with which children acquire new information (i.e., training responsiveness) rather than in how well they predict post-training independent performance. (p. 367)

<sup>1</sup> We excluded Byrne's work (e.g., Byrne, Fielding-Barnsley, & Ashley, 2000) because it conceptualizes DA as the student's rate of acquisition in response to schooling; it is not an assessment conducted to predict responsiveness to schooling. Therefore, as an assessment paradigm, Byrne's work is more similar to responsiveness-to-intervention than to DA.

### Purpose of the Present Study

As reflected in Day et al.'s (1997) concluding comments, additional work on DA is necessary, especially in light of Spector's (1992) promising findings. In the present study, the academic outcome was third-grade skill with word problems. Our DA extended the framework for considering type of DA task by employing actual math content that was not a precursor or foundational skill for solving word problems: three basic algebra skills. The question was whether a student's potential to learn algebra at the beginning of third grade forecasted their development of word-problem competence over the course of third grade. We note that although linguistic content is absent from the algebra skills assessed on the DA, algebra does require understanding of the relations among quantities, as is the case for solving word problems. Hence, a potentially important connection does exist between algebraic learning, as assessed on the DA task, and word-problem learning, as addressed in the 16-week treatment conditions (validated vs. conventional word-problems instruction).

We selected basic algebra skills as our DA content for the following reasons. First, we could safely assume that these skills were unfamiliar to third graders (i.e., the skills had not been introduced in school to students by the beginning of third grade and were not familiar from everyday life experiences). Second, the algebra skills were of sufficient difficulty that most third graders would not be able to solve the problems without assistance but could learn the skills with varying amounts of teaching. Third and relatedly, at the beginning of third grade, students should have mastered the simple calculation skills that we incorporated within the three algebra items. Fourth, we could delineate rules underlying the algebra skills, rules that could be used to construct clear explanations within a graduated sequence of prompts. Fifth, the graduated sequences of prompts for the three skills could be constructed in an analogous hierarchy, thereby promoting equal interval scaling of the DA scoring system. Sixth, the three skills were increasingly difficult (as established in pilot work) and later skills appeared to build on earlier skills; therefore, we hoped that transfer across the three algebra skills might facilitate better DA scores. Seventh, as noted, although linguistic content is absent from the algebra skills, algebra does require understanding of the relations among quantities, as is the case for solving word problems.

In the present study, we controlled for other variables that might be important in predicting outcome. First, we controlled for pretreatment performance on salient cognitive predictors of word-problem skill (language ability, attentive behavior, and nonverbal reasoning). Second, we controlled for students' pretreatment skill with calculations and word problems. Third, we extended prior work by also controlling for the nature of classroom instruction. Toward that end, on the basis of random assignment, students received conventional mathematical problem-solving instruction or research-validated schema-broadening instruction (e.g., Fuchs et al., *in press*), and we treated treatment condition as a competing predictor variable (see Method section for a description of these treatment conditions). Two other features of the present study are noteworthy. We examined word-problem outcome as a function of whether the word-problem measures could be considered near versus far transfer from instruction (i.e., the flexibility required to apply the content of the math word-problems curriculum). Also,

we relied on structural equation modeling, as did Day et al. (1997), to assess DA's added value. In the remaining section of this introduction, we briefly explain the basis for selecting language ability, attentive behavior, and nonverbal reasoning as the cognitive predictors of word-problem skill.

Prior work examining cognitive processes that underlie skill with word problems has recurrently identified three important dimensions: attentive behavior, nonverbal reasoning, and language ability. In studies involving attentive behavior, most work has focused on the inhibition of irrelevant stimuli, with mixed results. Passolunghi and colleagues ran a series of studies suggesting the importance of inhibition. For example, comparing good and poor problem solvers, Passolunghi, Cornoldi, and De Liberto (1999) found comparable storage capacity, with inefficiencies of inhibition (i.e., poor problem solvers remembered less relevant but more irrelevant information in math problems). In addition, Fuchs et al. (2005) and Fuchs et al. (2006) studied the role of attention more broadly and, in separate studies, found that a teacher rating scale of attentive behavior predicted the development of skill with word problems at first and third grades.

Nonverbal problem solving, or the ability to complete patterns presented visually, has also been identified as a unique predictor in the development of skill with word problems across first grade (Fuchs et al., 2005), a finding corroborated by Agness and McClone (1987). This is not surprising because word problems, where the problem narrative poses a question entailing relationships between numbers, appear to require conceptual representations, and the finding has been replicated as a unique predictor of concurrent word-problem skill at third grade (Fuchs et al., 2006).

Language ability also is important to consider given the obvious need to process linguistic information when building a problem representation of a word problem. Jordan, Levine, and Huttenlocher (1995) documented the importance of language ability when they showed that kindergarten and first-grade language-impaired children performed significantly lower than nonimpaired peers on word problems. Fuchs, Fuchs, Stuebing, Fletcher, Hamlett, and Lambert (2008) examined concurrent performance on nine cognitive dimensions with multiple measures of calculations skill and word-problem skill on a sample of 917 third graders representatively sampled from 89 classes. Students were classified as having difficulty with calculations, word problems, both domains, or neither domain. Multivariate profile analysis on the nine cognitive dimensions showed that specific calculations difficulty was associated with strength in language, whereas difficulty with word problems was associated with deficient language. We also note that language ability and nonverbal reasoning compose two major dimensions in some prominent assessments of intelligence.

Because these cognitive dimensions are established predictors of word-problem skill, they represent worthy competitors against DA for capturing variance in word-problem outcomes. In addition, these cognitive dimensions, while differing from DA in their demands, connect in transparent ways to word-problem skill or to learning in the general education context. Language, while not reflected in our algebra DA, is clearly involved in word problems, which are communicated via narratives. Nonverbal problem solving asks students to complete matrices presented visually, involving classification and analogy. Although this has no direct connection to our algebra DA, it is linked to word-problem skill, which requires students to connect novel problems with the word-

problem types for which they know solutions. Evidence suggests this occurs via classification and analogy (e.g., Cooper & Sweller, 1987). Attentive behavior asks teachers to judge students' ability to attend to detail, sustain attention, listen, follow directions, organize tasks, keep track of things, ignore extraneous stimuli, and remember daily activities. These ratings, which teachers formulate on the basis of observations of students in their classrooms, seem better connected to learning word problems in general education settings than in one-to-one testing situations like DA, where the tester can redirect and control inattentive behavior more effectively. Finally, we note that language and nonverbal reasoning are two major dimensions of general intelligence, which traditionally has been used to predict academic achievement (in fact, in the present study, the Vocabulary and Matrix Reasoning measures used to index language ability and nonverbal problem solving, respectively, constitute the two-subtest Wechsler Abbreviated Scale of Intelligence [WASI]; Psychological Corporation, 1999). For this additional reason, these constructs represent worthy competitors with DA in forecasting responsiveness to classroom word-problem instruction.

## Method

### Participants

With the exception of the DA, the data described in this article were collected as part of a prospective 4-year study assessing the effects of mathematical problem-solving instruction and examining the developmental course and cognitive predictors of mathematical problem solving. The data in the present article were collected with a subset of students in the 4th-year cohort of the larger study at the first and second assessment waves (at fall and spring of third grade). We sampled students from the 30 participating classrooms in nine schools (five Title I and three non-Title I). Classrooms had been randomly assigned to treatment conditions (conventional vs. validated schema-broadening instruction) within schools. There were 2–6 students per class.<sup>2</sup>

We sampled students for the present study from the cohort's 510 students with parental consent. The sampling process was designed to yield a representative sample. That is, from these 510 students, we randomly sampled 150 for participation, blocking within instructional condition (conventional math problem-solving instruction vs. schema-broadening math problem-solving instruction), within classroom, and within three strata: (a) 25% of students with scores 1 *SD* below the mean of the entire distribution on the Test of Computational Fluency (Fuchs, Hamlett, & Fuchs, 1990; see *Measures of Cognitive, DA, and Calculations Pretreatment Performance*), (b) 50% of students with scores within 1 *SD* of the mean of the entire distribution on the Test of Computational Fluency, and (c) 25% of students with scores 1 *SD* above the mean of the entire distribution on the Test of Computational Fluency. Of these 150 students, we have complete data for the variables reported in the present study on 122 children. The 122 included students were comparable to the remaining students on the study variables, with varying sample sizes depending on where missing data occurred. See Table 1 for descriptive information on performance variables for the sample of 122 children. Of these students, 67 (54.9%) were male, and 80 (67.0%) received subsidized lunch. Ethnicity was distributed as follows: 57 (47.5%) African Ameri-

can, 53 (43.4%) European American, 10 (8.3%) Hispanic, and 3 (2.5%) other. Two students (1.7%) were English language learners.

On the basis of random assignment, 61 students received conventional math problem-solving instruction (as determined by their core math program and teachers), and 61 received schema-broadening math problem-solving instruction that has been validated (i.e., five large-scale randomized control trials, published in peer-reviewed journals, have documented the efficacy of the intervention at third grade with similar populations of students; Fuchs et al., 2003a, 2003b; Fuchs, Fuchs, Finelli, et al., 2004; Fuchs, Fuchs, Prentice, et al., 2004; Fuchs et al., in press). In Table 1, we show performance variables by instructional condition. Of the 61 students in conventional math problem-solving instruction, 32 (52.5%) were male, and 39 (63.9%) received subsidized lunch. Ethnicity was distributed as follows: 32 (52.5%) African American, 25 (41.0%) European American, and 5 (8.2%) Hispanic. Two students (3.2%) were English language learners. Of the 61 students in validated, schema-broadening math problem-solving instruction, 35 (57.4%) were male, and 41 (67.2%) received subsidized lunch. Ethnicity was distributed as follows: 25 (41.1%) African American, 28 (45.9%) European American, 5 (8.2%) Hispanic, and 3 (4.9%) other. None was an English language learner.

### Procedure

We describe the subset of measures relevant to this research report. In October, the DA was administered individually in one 30- to 45-min session. In September and October, we administered measures of language and nonverbal reasoning (Woodcock Diagnostic Reading Battery [WDRB]—Listening Comprehension; Woodcock, 1997; Test of Language Development—Primary [TOLD] Grammatical Closure; Newcomer & Hammill, 1988; WASI Vocabulary; and WASI Matrix Reasoning) and math performance (Woodcock-Johnson III Tests of Cognitive Abilities [WJ III] Applied Problems; Woodcock, McGrew, & Mather, 2001) individually in two 45-min sessions. In October, we administered the Test of Algorithmic Word Problems (Fuchs et al., 2003a) in one 30-min large-group session, and we administered three tests of calculations skill (Addition Fact Fluency [Fuchs, Hamlett, & Powell, 2003], Subtraction Fact Fluency [Fuchs, Hamlett, & Powell, 2003], and Test of Mixed Algorithms [Fuchs et al., 1990]) in one 60-min large-group session. We also obtained scores on the previous spring's state assessment (Tennessee Comprehensive Assessment Program; CTB/McGraw-Hill, 2003) from teachers.

In March, five tests of word-problem skill were administered (Algorithmic Word Problems, Complex Word Problems, Real-World Problem Solving [all three from Fuchs et al., 2003a], and

<sup>2</sup> Concerning classroom as a potential source of dependency in the data, we calculated intraclass correlations (ICCs) for classrooms on the outcomes measures, which is where important context effects might be revealed. We found minimal ICCs for the far-transfer measures (.003–.03). By contrast, the ICCs for the near-transfer measures were sizeable (.5–.7). However, the ICCs for the near-transfer measures dropped to levels comparable to the far-transfer measures when the effects of treatment were controlled, as in the SEM models. So in the SEM models, variance in the outcomes is essentially at the individual not the classroom level, making it unnecessary to account for classroom in the SEM models.

Note. SBI = schema-broadening instruction; WASI = Wechsler Abbreviated Scale of Intelligence; TCAP = Tennessee Comprehensive Assessment Program; WJ = Woodcock-Johnson III Tests of Cognitive Abilities; WRMT-WID = Woodcock Reading Mastery Tests—Revised: Word Identification; SWAN = SWAN Rating Scale; DA = dynamic assessment; Iowa = Iowa Test of Basic Skills: Problem Solving and Data Interpretation.

WJ III Applied Problems). The first four were administered in two sessions in large groups. WJ III Applied Problems was administered individually in one session. We categorized the word-problem measures in terms of transfer distance (i.e., the distance from the types of word problems addressed during instruction and the degree of flexibility required in applying the word problems taught during instruction). Algorithmic Word Problems and Complex Word Problems were deemed near transfer. Real-World Problem Solving, WJ III Applied Problems, and the Iowa Test of Basic Skills: Problem Solving and Data Interpretation (Hoover, Dunbar, & Frisbie, 2001) were considered far transfer. (We elaborate on transfer distance for each measure in the measures section.)

Group and individual testing was conducted by trained university examiners, each of whom had demonstrated 100% accuracy during mock administrations. All individual sessions were audio-taped, and 19.9% of tapes, distributed equally across testers, were selected randomly for accuracy checks by an independent scorer. Agreement was between 98.7% and 99.9%. In October, classroom teachers completed the SWAN Rating Scale (Swanson, 2004), the measure of attentive behavior, on each student.

### Measures of Cognitive, DA, and Calculations Pretreatment Performance

**Language.** We used three measures of language skill to create a latent variable representing language. TOLD Grammatic Closure (Newcomer & Hammill, 1988) measures the ability to recognize, understand, and use English morphological forms. The examiner reads 30 sentences, one at a time; each sentence has a missing word. As per the test developers, for 8-year-olds, reliability is .88; the correlation with the Illinois Test of Psycholinguistic Ability Grammatic Closure (Kirk, McCarthy, & Kirk, 1968) is .88. Coefficient alpha on the representative sample was .76. The WDRB Listening Comprehension (Woodcock, 1997) measures the ability to understand sentences or passages. Students supply words missing from the end of each sentence or passage. The test begins with simple verbal analogies and associations and progresses to comprehension involving the ability to discern implications. Testing is discontinued after six consecutive errors. The score is the number of correct responses. As per the test developers, reliability is .80 at ages 5–18; the correlation with Woodcock-Johnson Psycho-Educational Battery—Revised (Woodcock & Johnson, 1989) is

.73. Coefficient alpha on the representative sample was .81. WASI Vocabulary (Psychological Corporation, 1999) measures expressive vocabulary, verbal knowledge, and foundation of information. The first four items present pictures; the student identifies the object in the picture. For remaining items, the tester says a word that the student defines. Testing is discontinued after five consecutive errors. As reported by Zhu (1999), split-half reliability is .86–.87 at ages 6–7; the correlation with Wechsler Intelligence Scale for Children (3rd rev.; Wechsler, 1991) Full Scale IQ is .72. Coefficient alpha on the representative sample was .78.

*Nonverbal problem reasoning.* WASI Matrix Reasoning (Psychological Corporation, 1999) measures nonverbal reasoning with pattern completion, classification, analogy, and serial reasoning. Examinees look at a matrix from which a section is missing and complete it. Testing is discontinued after four errors on five consecutive items or four consecutive errors. As per the test developer, reliability is .94 for 8-year-olds; the correlation with Wechsler Intelligence Scale for Children (3rd rev.) Full Scale IQ is .66. Coefficient alpha on the representative sample was .76.

*Attentive behavior.* The SWAN Inattentive subscale is a 9-item teacher rating scale. Items from the *Diagnostic and Statistical Manual of Mental Disorders* (4th ed.; American Psychiatric Association, 1994) criteria for attention-deficit/hyperactivity disorder are included. Items are rated on a 1–7 scale. We grouped items into triads (1–3, 4–6, 7–9) to form three observed attentive behavior variables for use in the structural equation modeling. The SWAN has been shown to correlate well with other dimensional assessments of behavior related to inattention (Swanson, 2004). Coefficient alpha in this study was .92 for items 1–3, .94 for items 4–6, and .94 for items 7–9.

*DA.* The DA addresses three algebra skills assumed to be novel because they have not been taught in school and because they do not routinely occur in children's extra-school experiences. The three algebra skills are (a) finding the missing variable in the first or second position in addition equations (e.g.,  $x + 5 = 11$  or  $6 + x = 10$ ), (b) finding  $x$  in multiplication equations (e.g.,  $3x = 9$ ), and (c) finding the missing variable in equations with two missing variables but with one variable then defined (e.g.,  $x + 2 = y - 1$ ;  $y = 9$ ). We refer to these three skills, respectively, as *DA Skill A*, *DA Skill B*, and *DA Skill C*.

Mastery of each DA skill is assessed before instructional scaffolding begins, and mastery testing recurs after each level of instructional scaffolding is completed. The mastery test comprises six items representing the skill targeted for mastery, with mastery defined as at least five items correct. The items on the test are never used for instruction but parallel instructional items; each time the six-item test is readministered for a given skill, a different form is used, although some items recur across forms. If, after 5 s, the student has not written anything and does not appear to be working, the tester asks, "Can you try this?"; if after another 15 s, the student still has not written anything and does not appear to be working, the tester asks, "Are you still working or are you stuck?" If the student responds that he/she is stuck, the tester initiates the first (or next) level of instructional scaffolding. If the student responds that he/she is still working but another 30 s pass without the student writing anything or working, the tester then initiates the first (or next) level of instructional scaffolding. If the student masters the skill (i.e., at least five items are answered correctly), the tester administers a generalization problem (i.e., for DA Skill

A:  $3 + 6 + x = 11$ ; for DA Skill B:  $14 = 7x$ ; for DA Skill C:  $3 + x = y + y$ ;  $y = 2$ ) and moves to the next DA skill. If the student does not master the skill (i.e., fewer than five items are answered correctly), the tester provides the first (or next) level of instructional scaffolding, or support, which is followed by the six-item test. The levels of instructional scaffolding gradually increase instructional explicitness and concreteness. If a student fails to answer at least five items correctly after the tester provides all five scaffolding levels for a given skill, the DA is terminated.

Scores range from 0 to 21, where 0 is the worst score (i.e., student never masters any of the three skills) and 21 is the best score (i.e., student masters each of the three skills on the pretest and gets every bonus problem correct). So, for each skill, there is a maximum of 7 points, awarded as follows: student masters skill on pretest = 6 points, student masters skill after Scaffolding Level 1 = 5 points; student masters skill after Scaffolding Level 2 = 4 points, student masters skill after Scaffolding Level 3 = 3 points, student masters skill after Scaffolding Level 4 = 2 points, student masters skill after Scaffolding Level 5 = 1 point, student never shows mastery = 0 points. In addition, if the student gets the generalization problem correct, 1 point is added, for the maximum score of 7 points for that DA skill.

To promote equal interval scaling, scaffolding levels for each of the three skills are structured analogously. Scaffolding levels, which range from incidental to explicit, are provided in the Appendix for DA Skill A. For this information on DA Skills B and C, contact Lynn S. Fuchs. Correlations with the previous year's math composite score on the state assessment (CTB/McGraw-Hill, 2003) were .57 for DA Skill A, .60 for DA Skill B, and .41 for DA Skill C.

*Calculations.* Three measures were used to create a latent variable representing calculation skill. Addition Fact Fluency (part of Grade 3 Math Battery; Fuchs, Hamlett, & Powell, 2003) comprises 25 addition fact problems with answers from 0 to 12 and with addends from 0 to 9. Problems are presented horizontally on one page. Students have 1 min to write answers. Percentage of agreement, on 20% of protocols by two independent scorers, was 99.9. Coefficient alpha for this sample was .92; criterion validity with the previous spring's TerraNova (CTB/McGraw-Hill, 2003) Total Math score was .53 for the 1139 students on whom we had TerraNova scores. Subtraction Fact Fluency (part of Grade 3 Math Battery; Fuchs, Hamlett, & Powell, 2003) comprises 25 subtraction fact problems with answers from 0 to 12 and with minuends/subtrahends from 0 to 18. Problems are presented horizontally on one page. Students have 1 min to write answers. Percentage of agreement, on 20% of protocols by two independent scorers, was 98.7. Coefficient alpha for this sample was .93, and criterion validity with the previous spring's TerraNova (CTB/McGraw-Hill, 2003) Total Math score was .51 ( $n = 1139$ ). The Test of Mixed Algorithms (Fuchs, Hamlett, & Fuchs, 1990) is a one-page test with 25 items that sample the typical second-grade computation curriculum, including adding and subtracting number combinations and procedural computation. Students have 3 min to complete as many answers as possible. Staff entered responses into a computerized scoring program on an item-by-item basis, with 15% of tests reentered by an independent scorer. Data-entry agreement was 99.7. Coefficient alpha for this sample was .94, and criterion validity with the previous spring's TerraNova (CTB/McGraw-Hill, 2003) Total Math score was .60 ( $n = 1139$ ).

### Measures of Word-Problem Skill

We measured pretreatment word-problem skill using Algorithmic Word Problems. We measured posttreatment word-problem outcomes using Algorithmic Word Problems, Complex Word Problems, Real-World Problem Solving, WJ III Applied Problems, and Iowa Test of Basic Skills: Problem Solving and Data Interpretation.

Four independent judges classified the five word-problem outcome measures in terms of transfer distance from the instruction provided in schema-broadening math problem-solving instruction (i.e., the flexibility required to apply the content of the math word-problem curriculum) into two classes: near transfer versus far transfer. Agreement was 100%. We describe the word-problem outcomes in terms of near-transfer measures (all novel problems but structured similarly to problems used for instruction) versus far-transfer measures (all novel problems, not structured similarly to problems used for instruction). Schema-broadening instruction (SBI) focused on four word-problem types, chosen from the district curriculum to ensure that conventional math problem-solving instruction students had instruction relevant to the study. The four problem types were “shopping list” problems (e.g., “Joe needs supplies for the science project. He needs 2 batteries, 3 wires, and 1 board. Batteries cost \$4 each, wires cost \$2 each, and boards cost \$6 each. How much money does he need to buy supplies?”), “half” problems (e.g., “Marcy will buy 14 baseball cards. She’ll give her brother half the cards. How many cards will Marcy have?”), step-up function or “buying bags” problems (e.g., “José needs 32 party hats for his party. Party hats come in bags of 4. How many bags of party hats does José need?”), and two-step “pictograph” problems (e.g., “Mary keeps track of the number of chores she does on this chart [pictograph is shown with label: each picture stands for 3 chores]. She also took her grandmother to the market 3 times last week. How many chores has Mary done?”). In addition, SBI was designed to broaden schemas, with each problem varying the cover story and one of the four transfer features, which change a problem without altering its type or solution: a problem with unfamiliar vocabulary, posing an additional question, incorporating irrelevant information, or combining problem types.

*Near-transfer word problems.* Algorithmic Word Problems (Fuchs et al., 2003a) comprises 10 word problems each of which requires 1–4 steps. The measure samples the four problem types that correspond to SBI and that are incorporated within conventional classroom instruction: shopping list, half, buying bags, and pictograph problems. The tester reads each item aloud while students follow along on their own copies of the problems; the tester progresses to the next problem when all but 1–2 students have their pencils down, indicating they are finished. Students can ask for rereading(s) as needed. The maximum score is 44. We used two alternate forms; the problems in both forms required the same operations, incorporated the same numbers, and presented text with the same number/length of words. In half the classes in each treatment condition, we used Form A at pretest and Form B at posttest; in the other half, forms were reversed. For the representative sample, Cronbach’s alpha was .85, and criterion validity with the previous spring’s TerraNova (CTB/McGraw-Hill, 1997) Total Math score was .58 for the 844 students on whom we had TerraNova scores. Interscorer agreement, computed on 20% of protocols by two independent scorers, was .984.

Complex Word Problems (Fuchs et al., 2003a) comprises nine problems representing the same four problem types within more complex contexts, which incorporate the four transfer features explicitly taught within SBI: (a) adding multiple quantities of items with different prices, with information presented in bulleted format and with a selection response format; (b) adding multiple quantities of items with different prices, also asking for money left at the end; (c) a step-up function problem with irrelevant information; (d) a step-up function that requires students to compare the prices of two packaging options; (e) a half problem using the words *share equally* instead of *half*; (f) a pictograph/adding problem asking for money left at the end; (g) a pictograph/adding problem comparing two quantities; (h) a problem with irrelevant information that combined multiple quantities with different prices and pictograph/adding; and (i) a problem with irrelevant information that combined multiple quantities with different prices and a step-up function. The tester reads each item aloud while students follow along on their own copies of the problems; the tester progresses to the next item when all but 1–2 students have their pencils down, indicating they are finished. Students can ask for rereading(s) as needed. The maximum score is 79. For the representative sample, Cronbach’s alpha was .88, and criterion validity with the previous spring’s TerraNova Total Math Score was .55 for the 844 students on whom we had TerraNova scores. Interscorer agreement, computed on 20% of protocols by two independent “blind” scorers, was .983.

*Far-transfer word problems.* Real-World Problem Solving (Fuchs et al., 2003a) simultaneously assesses transfer of all four problem types and all four transfer features addressed in SBI. Also, to decrease association between the task and classroom or tutoring SBI, far transfer was formatted to look like a commercial test (printed with a formal cover, on green paper, with photographs and graphics interspersed throughout the test booklet). Two assessments were constructed as alternate forms: Although the context of the problem situations differed, the structure of the problem situation and the questions were identical, and the problem solutions and reading demands were equivalent.

Performance was scored according to a rubric with four dimensions: conceptual underpinnings, computational applications, problem-solving strategies, and communicative value. The original rubric (Kansas State Board of Education, 1991) scored responses on a 6-point scale. To enhance reliability, we awarded points on a finer basis (e.g., the problem-solving strategies score included points for finding relevant information, accumulating to a total, showing all computation, working the answer in distinct multiple parts, labeling at least half of the multiple parts, and labeling work with monetary and operation signs). Across the four questions and four scoring dimensions, the maximum score is 72. On this sample, Cronbach’s alpha was .91 at pretest; .94 at posttest; concurrent validity with WJ III Applied Problems (Woodcock et al., 2001) was .47 at pretest and .61 at posttest. Interscorer agreement, computed on 20% of protocols by two independent “blind” scorers, was .987 at pretest and .949 at posttest. Given the deleterious effects of student unfamiliarity with performance assessments (Fuchs, Fuchs, Karns, et al., 2000), research assistants delivered a 45-min “test-wiseness” lesson before pre- and posttesting in all conditions. (The mean score across immediate, near, and far transfer correlated .62 with WJ III Applied Problems [Woodcock et al., 2001] at pretest and .57 at posttest.)

WJ III Applied Problems (Woodcock et al., 2001) measures skill in analyzing and solving practical math problems with 60 items. The tester orally presents items involving counting, telling time or temperature, and problem solving. The word problems addressed a range of problem types, none of which was directly addressed within SBI. Testing is discontinued after six consecutive errors. The score is the number of correct items. As reported by McGrew and Woodcock (2001), 1-year test-retest reliability is .85; the ratio of true score variance to observed variance is .88-.91. Coefficient alpha on this sample was .85.

*Iowa Test of Basic Skills: Problem Solving and Data Interpretation.* With Iowa Test of Basic Skills: Problem Solving and Data Interpretation (Hoover et al., 2001), students solve 24 word problems and use data presented in tables and graphs to solve word problems. The problems on this test were related only marginally to the content of SBI. Five problems included pictographs embedded within problem types not addressed in SBI. One problem incorporated irrelevant information, again embedded in a problem type not addressed in SBI. For Grades 1-5, Kuder-Richardson Formula 20 is .83-.87. In this study, coefficient alpha was .86.

### Instruction

On the basis of random assignment, students received conventional math problem-solving or validated SBI. We describe these conditions briefly. For additional information, see Fuchs et al. (in press). The problem types were already described under *Measures of Word-Problem Skill*.

*Conventional instruction.* To guide instruction relevant to the four problem types, conventional instruction relied primarily on Houghton Mifflin Math (Greenes et al., 2007). Instruction addressed one problem type at a time (as did SBI) and focused on the concepts underlying the problem type. In addition, a prescribed set of problem-solution rules was taught, with explicit steps for arriving at solutions to the problems presented in the narrative. There was no attempt to broaden students' schemas for these problem types to address transfer. However, in comparison to the classroom SBI, classroom control group instruction provided more practice in applying problem-solution rules and provided greater emphasis on computational requirements. Conventional instruction was explicit and relied on worked examples, guided group practice, independent work with checking, and homework. In addition, conventional instruction (as well as SBI) incorporated a 3-week researcher-designed and delivered general problem-solving strategies unit.

*General problem-solving strategies instruction (conventional instruction and SBI).* Conventional instruction and SBI students received a researcher-designed 3-week (2 lessons per week) instructional unit on general math problem-solving strategies, which was conceptually unrelated to SBI. It addressed making sure answers make sense; lining up numbers from text to perform math operations; checking computation; and labeling work with words, monetary signs, and mathematical symbols. These six lessons, each lasting 30-40 min, relied on worked examples with explicit instruction, dyadic practice, independent work with checking, and homework, for a total of 210 min. For a manual with general problem-solving strategies, contact Lynn S. Fuchs.

*SBI.* For an SBI manual, contact Lynn S. Fuchs. SBI students received the 3-week general math problem-solving unit as well as four researcher-designed 3-week SBI units. Each SBI unit com-

prised six sessions. Also, two cumulative review sessions were delivered the week after winter break. In each unit, Sessions 1 and 5 lasted about 40 min; the others lasted about 30 min. This totaled 200 min per unit and 856 min across the units (including the two cumulative review sessions). Each 3-week unit addressed one of the four problem types: shopping list, buying bag, half, and pictograph.

Within each unit, the sequence of lessons was as follows. In Sessions 1-4, problem-solution instruction was delivered, using problems that varied only cover stories. A poster listing the steps of the solution method was displayed in the classroom. In Session 1, teachers addressed the underlying concepts and structural features for the problem type, presented a worked example, and, as they referred to the poster, explained how each step of the solution method had been applied in the example. Students responded frequently to questions. After reviewing the concepts and presenting several worked examples in this way, teachers shared partially worked examples while students applied the solution steps. Students then completed 1-4 problems in dyads, where stronger students helped weaker students solve problems and check work with answer keys. Sessions 2-4 were structured similarly, with a greater proportion of time spent on partially worked examples and dyadic practice. Also, at the end of Sessions 2-4, students completed one problem independently, the teacher checked work against an answer key, and students graphed scores.

Sessions 5-6 were designed to broaden schemas, with each problem varying the cover story and one of the four transfer features addressed in SBI. Teachers first taught the meaning of the word *transfer*. Then, they taught the four transfer features, which change a problem without altering its type or solution: A familiar problem type, for which a solution is known, can use unfamiliar vocabulary, can pose an additional question, can incorporate irrelevant information, can combine problem types. A poster, "Transfer: Ways Problems Change," was displayed. In Session 5, teachers explained the poster, illustrating each transfer feature with a worked example. They gradually moved to partially worked examples. Then, students worked in pairs to apply the solution method to problems that varied transfer features. In Session 6, teachers reviewed the four transfer features using similar procedures, except students spent more time working in dyads and then completed a problem independently, scored work against a key, and graphed scores.

*Delivery.* Each research assistant, all full-time research employees or graduate students in the College of Education, had responsibility for students in both conditions. All sessions were scripted to ensure consistency of information; however, to permit natural teaching styles, scripts were studied, not read. To ensure comparable mathematics instructional time across conditions, SBI sessions occurred within the confines of the mathematics instructional block. At the end of the study, classroom teachers reported the number of minutes per week they spent on math, including time on SBI, and the amount of instructional time for conventional versus SBI students was comparable and similar.

*Treatment fidelity.* Prior to the first delivery of each session, research assistants agreed on the essential information in the script and made a checklist of points. Each session was audiotaped. At the study's end, two research assistants independently listened to tapes while completing the checklist to identify the percentage of points addressed. We sampled tapes so that, within conditions,

research assistants and lesson types were sampled equitably. In conventional instruction, 1–2 tapes were sampled per class (for Unit 1); in SBI, 6–7 tapes were sampled per class (distributed equally across Units 1–5). Intercoder agreement, calculated on 20% of the sampled tapes, was 97.2%. The mean percentage of points addressed was 98.34 ( $SD = 3.16$ ) for conventional instruction and 95.82 ( $SD = 2.46$ ) for SBI.

## Data Analysis and Results

### Descriptive Data

Data analysis progressed in two stages. First, the measurement models for pretreatment and posttreatment measures were estimated using confirmatory factor analysis. Second, various relational models were tested using structural equation modeling. Prior to model estimation, the data were preanalyzed to identify outliers and estimate departures from univariate and multivariate normality. Univariate plots revealed no significant outliers (plus or minus three standard deviations from the mean of the sample on that variable). PRELIS 8.7 (Jöreskog & Sörbom, 2004) was used to explore univariate and multivariate normality. In the case of univariate normality, PRELIS provides separate estimates of skew and kurtosis for each variable with accompanying  $p$  values. Several variables exhibited significant skew (Complex Word Problems, Subtraction Fact Fluency, and DA Skill A) and kurtosis (Real-Word Problem Solving and Subtraction Fact Fluency). Mardia's statistic for multivariate normality revealed significant multivariate nonnormality for skew ( $z = 2.361$ ,  $p = .018$ ) but not for kurtosis ( $z = 0.787$ ,  $p = .431$ ). To examine the extent to which nonnormality affects the chi-square fit statistic, models were constructed using maximum likelihood versus a scaled chi-square estimated with robust standard errors using the method developed by Satorra and Bentler (1994) as suggested by West, Finch, and Curran (1994). A scaling correction factor was calculated representing the standard chi-square divided by the scaled chi-square. Scaling correction factors ranged from 0.97 to 1.05 across models suggesting little difference between the standard and scaled chi-square values. Thus, we concluded that multivariate nonnormality had little effect on the estimated chi-square in this study. For the remainder of the article, we report results from models estimated with LISREL 8.7 (Jöreskog & Sörbom, 2004) using a maximum likelihood estimation on the sample of participants with complete data. There is growing evidence to suggest that maximum likelihood-based fit indices outperform other estimation procedures and perform reasonably well with small sample sizes even when distributions are less than optimal (see Hu & Bentler, 1998).

In Table 1, we show means and standard deviations to describe the sample on pretreatment performance variables and on the math outcome variables. We provide this for the total sample and by instructional condition. In Table 2, we show correlations among the pretreatment performance and the math outcome study variables for the total sample. We note that all observed (manifest) variables were transformed to  $z$  scores prior to structural equation modeling. Also in Table 2, we show correlations between treatment condition (validated SBI vs. conventional) and the math outcome study variables (we do not provide the correlations between treatment condition and pretreatment performance variables because treatment was randomized).

### *Pretreatment Measurement Model: Is DA a Distinct Dimension of Pretreatment Ability?*

Our pretreatment measurement model included six dimensions of pretreatment performance. The first latent variable, language ability, comprised TOLD Grammatical Closure, WDRB Listening Comprehension, and WASI Vocabulary. The second dimension, attentive behavior, included three clusters of items from the SWAN (Items 1–3, Items 4–6, and Items 7–9). The third latent variable, DA, comprised DA Skill A, DA Skill B, and DA Skill C. The fourth latent variable, calculations skill, incorporated Addition Fact Fluency, Subtraction Fact Fluency, and Test of Mixed Algorithms. The fifth latent variable, a single manifest variable, WASI Matrix Reasoning, was used to measure nonverbal reasoning. Within structural equation modeling, the default is to set the error variance to zero for manifest variables. Instead of using the default, we accounted for measurement error in nonverbal reasoning using the alpha coefficient for the present sample ( $r = .94$ ) to specify the error variance. A reliability of .94 is equivalent to an error variance of 0.06 times the variance of nonverbal reasoning, which in this case was 1.0 (for details, see MacCallum, 1995). The final latent variable, Algorithmic Word Problems, was also a single manifest variable. It was used to measure pretreatment word-problem skill. To account for measurement error in word-problem skill, we used the alpha coefficient for the present sample ( $r = .84$ ) to specify the error variance of 0.16.

See Table 3 for correlations among the pretreatment measurement model latent traits. All observed variables loaded substantially and reliably onto their respective factors (standardized coefficients: .44 to .98,  $ps < .001$ ). Because this base measurement model included the greatest number of estimated parameters (compared to the competing measurement models), it provided the best characterization of the data and served as a basis for comparing the competing, more parsimonious models. Chi-square goodness-of-fit statistic plus four different fit indices (representing Type 1–3 fit and absolute-fit indices) are provided. Jaccard and Wan (1996) and Kline (1998) suggested use of multiple fit indices to reflect diverse criteria. Hu and Bentler (1998) recommended with maximum likelihood estimation methods that standardized root-mean-square residual (SRMR; absolute fit) be reported and supplemented with normed fit index (NFI; Type 1 fit), nonnormed fit index (NNFI; Type 2 fit), and comparative fit index (CFI; Type 3 fit). In evaluating a model, adequate fit is indicated by a nonsignificant chi-square test; NFI, NNFI, and CFI exceeding .95; and a SRMR of less than .08 (see Hu & Bentler, 1998). The base six-factor measurement model accounted well for the data structure,  $\chi^2(64, N = 122) = 58.31$ ,  $p = .6771$ ; NFI = .965; NNFI = 1.000; CFI = 1.000; and SRMR = 0.0389 (see Pretreatment Measurement Model 1 in Table 4 and Figure 1).

To assess the distinctiveness of DA as a pretreatment performance dimension, we compared this base measurement model against five more parsimonious, five-factor measurement models. The utility of one model to explain data can be compared statistically against the utility of other models in which it is nested by using a chi-square difference tests (i.e.,  $\Delta\chi^2$ ). The base model always yields the best fit because it includes the most estimated parameters and is therefore the least restrictive model. However, in the interest of parsimony, a more restrictive nested model that fails to yield a significantly worse fit is accepted as superior.

Note. WJ = Woodcock-Johnson III Tests of Cognitive Abilities.

<sup>a</sup> Treat = treatment condition, where 1 = conventional instruction on word problems and 2 = validated SBI on word problems. <sup>b</sup> The correlation between treatment condition and the dimensions of pretreatment performance were set to zero, given random assignment to treatment.

Table 3  
Latent Trait Correlations

Variable	L	NVR	A	DA	WP
Pretreatment					
Language (L)	—				
Nonverbal reasoning (NVR)	.31	—			
Attention (A)	.48	.18	—		
Dynamic assessment (DA)	.60	.64	.50	—	
Calculations (C)	.31	.33	.52	.67	—
Word problems (WP)	.52	.40	.45	.68	.46

Note. The correlation between the near- and far-transfer outcome latent variables was .49.

In each of the five competing five-factor measurement models, we merged DA with one other dimension of pretreatment performance. So, for example Pretreatment Measurement Model 2 (see Table 4) included a separate attentive behavior factor, a separate calculations skill factor, a separate nonverbal reasoning factor, pretreatment word-problem skill, and a factor in which indices of language and DA loaded together (on a single factor). In Pretreatment Measurement Models 3, 4, 5, and 6 (see Table 4), DA was combined with one of the other pretreatment performance dimensions. Finally, we assessed a most parsimonious model, in which all indices were loaded onto one single factor (see Pretreatment Measurement Model 7 in Table 4). Each of these modified, more parsimonious measurement models yielded a significantly worse fit of the data compared to the base measurement model, as reflected in the significant  $\Delta\chi^2$  values in Table 4. We therefore concluded that DA measured a distinct dimension of pretreatment ability, and we incorporated all six dimensions of pretreatment ability into our structural model to predict word-problem outcome.

*Posttreatment Measurement Model: Are Near- and Far-Transfer Distinct Dimensions of Posttreatment Mathematics Word-Problem Skill?*

Our posttreatment measurement model included two dimensions of posttreatment word-problem skill. The first latent variable, near-transfer word problems, comprised Algorithmic Word Problems and Complex Word Problems. The second dimension, far-transfer word problems, included Real-World Word Problems, the Iowa, and WJ III Applied Problems. See Table 3 for correlations among the posttreatment measurement model latent traits. All observed variables loaded substantially and reliably onto their respective factors (standardized coefficients: .69 to .89,  $ps < .001$ ). The two-factor solution (near-transfer and far-transfer) accounted well for the data structure,  $\chi^2(4, N = 122) = 6.57, p = .154$ ; NFI = .981; NNFI = .983; CFI = .993; and SRMR = 0.0323 (see Posttreatment Measurement Model 1 in Table 4).

We contrasted this base measurement model with an alternative two-factor model comprising a simple word-problem latent variable (the Iowa and Algorithmic Word Problems) and a complex word-problem latent variable (comprised of Complex Word Problem, Real-World Word Problems, and WJ III Applied Problems). The same four independent judges who had classified near versus far transfer reclassified the measures in terms of simple versus complex. This alternative represented a theoretically different means to represent the factor structure of the word-problem outcome measures. This model fit substantially worse than the base model,  $\chi^2(4, N = 122) = 92.61, p = .0000$ ; NFI = .729; NNFI = .472; CFI = .736; and SRMR = 0.1456. (A chi-square difference score could not be used because these models are not nested.). The two-factor near- and far-transfer model included more estimated parameters than the competing measurement model; therefore, it provided the better characterization of the data and served as a basis for comparing the competing, more parsimonious model.

\*  $p < .001$ .

## Pretreatment Measurement Model

## Posttreatment Measurement Model

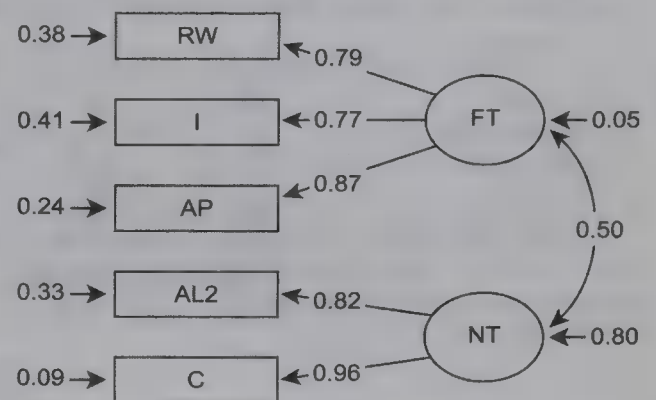

Figure 1. Pretreatment and posttest measurement models. Left: The base pretreatment measurement model, which incorporated each of the six dimensions of pretreatment ability measured in September and October: language ability (Test of Language Development—Primary Grammatical Closure [GC], Woodcock Diagnostic Reading Battery—Listening Comprehension [LC]), and Wechsler Abbreviated Scale of Intelligence [WASI] Vocabulary [V]), nonverbal reasoning (WASI Matrix Reasoning [MR]), attentive behavior (SWAN Rating Scale [SWAN 1-3, SWAN 4-6, SWAN 7-9]), Dynamic Assessment (DA1, DA2, DA3), calculations skill (Addition Fact Fluency from the Grade 3 Math Battery [A], Subtraction Fact Fluency from the Grade 3 Math Battery [S], Test of Mixed Algorithms [M]), word-problem skill (Algorithmic Word Problems [AL1]). Right: The two dimensions of posttreatment word-problem outcome measured in March: far-transfer word problems (Real-World Problem Solving [RW], the Iowa Test of Basic Skills: Problem Solving and Data Interpretation [I], and Woodcock-Johnson III Applied Problems [AP]), and near-transfer word problems (Algorithmic Word Problems [AL2] and Complex Word Problems [C]). LANG = language; NVR = nonverbal reasoning; ATTN = attention; CALC = calculation; WP = word-problem skill; FT = far-transfer word problems; NT = near-transfer word problems.

We then assessed whether both dimensions (near- vs. far-transfer) of posttreatment word-problem skill were necessary, by comparing this base measurement model against a more parsimonious, one-factor measurement model, which yielded a significantly worse fit of the data as reflected in the significant  $\Delta\chi^2$  value for Posttreatment Measurement Model 2 in Table 4. We therefore concluded that both dimensions of posttreatment word-problem skill (near- and far-transfer) were necessary, and we incorporated both dimensions into our structural model.

### Structural Model: Assessing the Predictors of Word-Problem Outcome Skill

Because few studies of this type have been conducted, we took an exploratory approach to model building. We first assessed the least parsimonious structural model. In this base model, each of the six dimensions of pretreatment performance (measured in September and October) plus treatment was included as a predictor of near-transfer word-problem skill and of far-transfer word-problem

Table 5

outcome (measured in March; see Table 5 and Figure 2, Full Model). In this model (and in all subsequent nested structural models), we set the correlation between treatment and the dimensions of pretreatment performance to zero, given random assignment to treatment. (The other dimensions of pretreatment performance were allowed to correlate freely.) As shown in Table 5, the model provided a good fit with the data,  $\chi^2(143, N = 122) = 169.61, p = .0637$ ; NFI = .950; NNFI = .986; CFI = .989; and SRMR = 0.0758. Treatment was the only significant predictor of near transfer. DA, pretreatment word-problem skill, and language were significant predictors of far transfer.

We then contrasted three alternative, more parsimonious structural models. In each of these models, treatment was retained as a predictor of outcome. In Models 2 and 3, we considered whether DA was in fact necessary to forecast word-problem outcomes or whether other dimensions of pretreatment ability function well without the inclusion of DA. Alternatively, it is possible that DA, in combination with treatment, is sufficient to account for the data structure in predicting word-problem outcomes, without including pretreatment cognitive abilities or pretreatment math skills. This was assessed in Model 4.

Specifically, in Model 2, the pretreatment cognitive dimensions and treatment were examined as the sole pretreatment predictors of outcome (see Cognitive Model in Table 5 and Figure 2). Given prior work establishing language (Fuchs et al., 2008; Jordan et al., 1995), nonverbal reasoning (Fuchs et al., 2005; 2006; Agness & McClone 1987), and attentive behavior (Fuchs et al., 2005; 2006; Passolunghi et al., 1999) as predictors of word-problem skill, we deemed it possible that the cognitive predictors and treatment alone would suffice in accounting for outcomes. If this Cognitive Model did not produce a significantly worse fit of the data structure compared to the base model, then assessing pretreatment foundational math skills and DA would be unnecessary, thereby providing a more parsimonious procedure for predicting outcome and undermining the importance of DA.

In Model 3, pretreatment math skills (on calculations and word problems) and treatment were considered as the sole predictors of near- and far-transfer (see Math Model in Table 5 and Figure 2). Given the transparent nature of the relation of pretreatment calculations skill and pretreatment word-problem skill to the word-problem outcomes, as well as prior work showing that pretreatment skill is often the best predictor of learning, we deemed it possible that these foundational math skills, along with treatment, would be sufficient to account for word-problem outcomes. Again,

if this Math Model did not produce a significantly worse fit of the data structure compared to the base model, then assessing the pretreatment cognitive abilities and DA would be unnecessary, consequently providing a more parsimonious approach for predicting outcome and undermining the importance of DA.

By contrast, in Model 4, we examined whether DA (along with treatment) might be sufficient to forecast near- and far-transfer word-problem outcome (see DA Model in Table 5 and Figure 2). As with the previous models, if the DA Model did not produce a significantly worse fit of the data structure compared to the base model, then assessing pretreatment cognitive abilities and pretreatment foundational skills would be unnecessary, hence providing a more parsimonious procedure for predicting outcome. This would demonstrate DA's power as a predictor of outcome even further than the base model, in which DA is one of three significant predictors of far-transfer outcome.

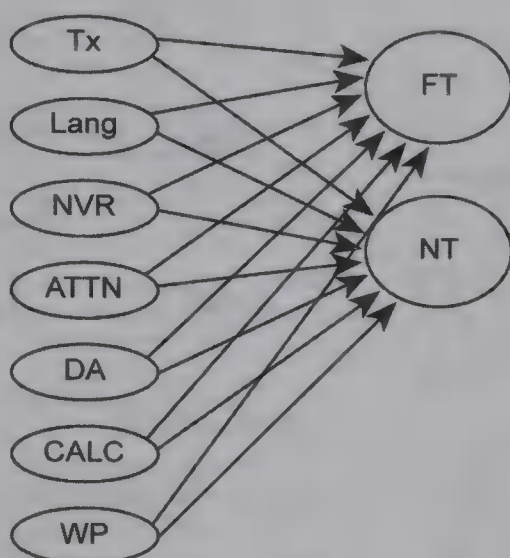

As shown in Table 5, each of these four nested, contrasting models produced a significantly worse fit of the data, suggesting that the full model is the best representation of the data structure. Figure 3 shows the full model with all coefficients specified (bolded, asterisked coefficients are *p* < .001).

Then, in the interest of reducing the parameter-to-sample-size ratio, we ran a trimmed model, deleting paths with standardized coefficients of less than .10. This trimmed model also provided a good fit with the data (see Figure 4 and last line of Table 5). Because there was no appreciable change in fit when moving from the full to the trimmed model, the simpler model is preferred. The coefficients in the full and trimmed models were highly similar, except that the path from calculations skill to near-transfer word problems increased from .14 to a significant .23 in the trimmed model.

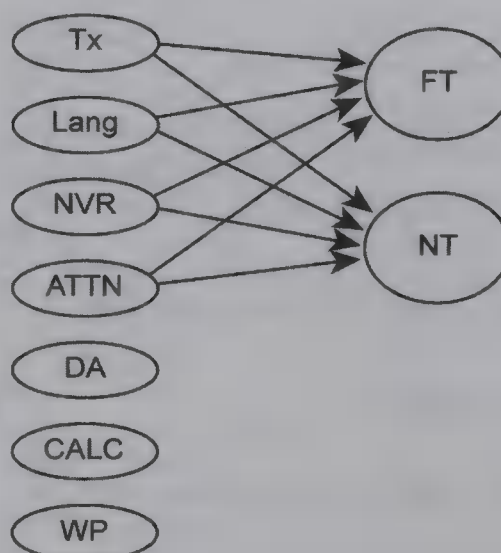

Discussion

We extended prior work on DA in several ways. First, earlier studies formulated DA tasks to address general cognitive abilities (e.g., Day et al., 1997; Speece et al., 1990) or a cognitive ability specifically linked to performance in the academic domain (e.g., Spector, 1992; Swanson & Howard, 2005). In the present study, by contrast, we centered DA on students' potential to learn algebra, which is neither a general cognitive ability nor a precursor to third-grade word-problem skill. In fact, skill with algebra is not even considered foundational to third-grade word-problem skill and instead represents novel academic content within the same broad academic area (mathematics). The potential advantage of

## 4: DA Model

*Figure 2.* Four structural models predicting pretreatment performance (measured in September and October) plus treatment to posttreatment near- and far-transfer outcomes (measured in March). The Full (base) Model is the least parsimonious structural, in which each of the six dimensions of pretreatment performance plus treatment was included as a predictor of outcomes. Each of the subsequent (nested) models is more parsimonious. In the Cognitive Model, pretreatment cognitive dimensions and treatment were examined as the sole predictors of outcomes. In the Math Model, pretreatment calculations and word-problem skill and treatment were considered as the sole predictors of outcomes. In the dynamic assessment (DA) Model, pretreatment DA and treatment were examined as the sole predictors of outcomes. Tx = treatment; Lang = language (Test of Language Development—Primary Grammatic Closure, Woodcock Diagnostic Reading Battery—Listening Comprehension, and Wechsler Abbreviated Scale of Intelligence [WASI] Vocabulary); NVR = nonverbal reasoning (WASI Matrix Reasoning); ATTN = attention (SWAN Rating Scale); DA = dynamic assessment; CALC = calculations skill (Addition Fact Fluency from the Grade 3 Math Battery, Subtraction Fact Fluency from the Grade 3 Math Battery, Test of Mixed Algorithms); WP = word-problem skill (Algorithmic Word Problems); FT = far-transfer word problems (Real-World Problem Solving, the Iowa Test of Basic Skills: Problem Solving and Data Interpretation, and Woodcock-Johnson III Applied Problems); NT = near-transfer word problems (Algorithmic Word Problems and Complex Word Problems).

using a DA task with novel academic content, such as algebra at third grade, is that it increases the probability that students' DA performance is attributable to their potential to learn new content rather than to existing ability to perform the DA task. In fact,

among the 122 participants, only 2 students exhibited mastery on all three DA skills prior to the introduction of scaffolded instruction (another 2 exhibited mastery on two of the three skills prior to scaffolded instruction, and another 34 exhibited mastery on one of

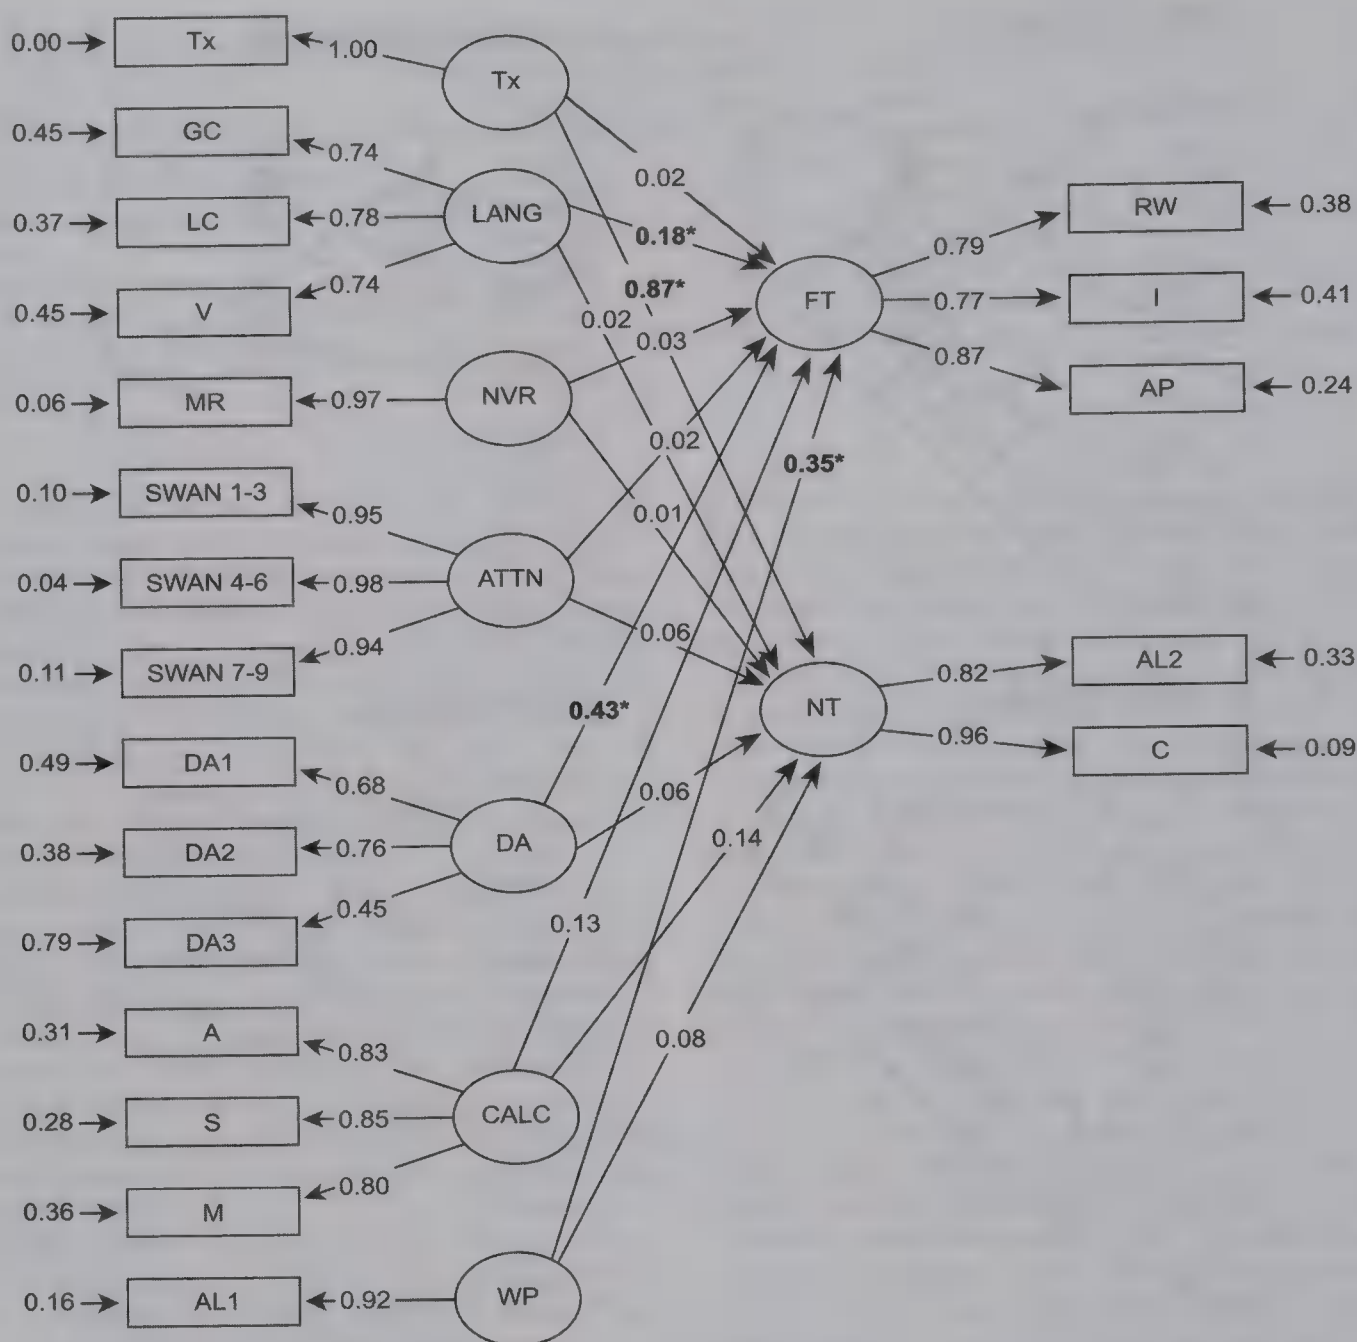

Figure 3. The full SEM with all coefficients specified. Left: The six dimensions of pretreatment ability measured in September and October are language ability (Test of Language Development—Primary Grammatical Closure [GC], Woodcock Diagnostic Reading Battery—Listening Comprehension [LC]), and Wechsler Abbreviated Scale of Intelligence [WASI] Vocabulary [V]), nonverbal reasoning (WASI Matrix Reasoning [MR]), attentive behavior (SWAN Rating Scale [SWAN 1-3, SWAN 4-6, SWAN 7-9]), Dynamic Assessment (DA1, DA2, DA3), calculations skill (Addition Fact Fluency from the Grade 3 Math Battery [A], Subtraction Fact Fluency from the Grade 3 Math Battery [S], Test of Mixed Algorithms [M]), word-problem skill (Algorithmic Word Problems [AL1]). Middle: Tx = treatment; Lang = language (Test of Language Development—Primary Grammatical Closure, Woodcock Diagnostic Reading Battery—Listening Comprehension, and WASI Vocabulary); NVR = nonverbal reasoning (WASI Matrix Reasoning); ATTN = attention (SWAN Rating Scale); DA = dynamic assessment; CALC = calculations skill (Addition Fact Fluency from the Grade 3 Math Battery, Subtraction Fact Fluency from the Grade 3 Math Battery, Test of Mixed Algorithms); WP = word-problem skill (Algorithmic Word Problems); FT = far-transfer word problems (Real-World Problem Solving, the Iowa Test of Basic Skills: Problem Solving and Data Interpretation, and Woodcock-Johnson III Applied Problems); NT = near-transfer word problems (Algorithmic Word Problems and Complex Word Problems). Right: The two dimensions of posttreatment word-problem outcome measured in March: far-transfer word problems (Real-World Problem Solving [RW], the Iowa Test of Basic Skills: Problem Solving and Data Interpretation [I], and Woodcock-Johnson III Applied Problems [AP]), and near-transfer word problems (Algorithmic Word Problems [AL2] and Complex Word Problems [C]). \*  $p < .001$ .

the three skills prior to scaffolded instruction). The remaining 84 students failed to exhibit mastery on any of the skills prior to scaffolded instruction. At the same time, it is important that the novel academic content connects in some important ways to the predicted learning outcome. In designing this study's DA as a method of forecasting development of word-problem skill, we hypothesized a connection between algebraic cognition and word-problem skill because (a) although linguistic content is absent from algebra, algebra does require understanding of relations among quantities, as is the case for solving word problems, and (b) some research (e.g., Fuchs, Seethaler, et al., 2008) shows that algebra can be used to develop students' word-problem skill, even in the primary grades.

In addition, we extended prior DA work in terms of the scope of the variables we considered as competitors to DA in predicting outcome. That is, we incorporated the nature of treatment into the prediction model, even as we simultaneously included static cognitive abilities as well as foundational math skill (on calculations as well as word problems) to predict outcomes that were proximal to as well as distal from the instruction students received in school. Our pretreatment measurement modeling supported DA as representing a dimension of pretreatment ability distinct from existing language ability, nonverbal reasoning, attentive behavior, and math skill. This finding echoes the work of Day et al. (1997) conducted with preschoolers, who found that the measurement model that retained DA as a construct separate from pre-DA provided better fit of the data. Together, Day et al.'s and our pretreatment measurement modeling indicates that DA may represent an aspect of students' learning potential that is distinct from conventional static measures. This makes sense because static assessment quantifies already-developed abilities that are influenced by environmental factors such as educational opportunity in school, parental support, and test-taking skills (Grigorenko & Sternberg, 1998), whereas DA measures a student's potential to learn. In this way, findings provide support for Vygotsky's (1978) concept of the zone of proximal development, or the distance between a child's realized developmental level as assessed by independent performance and that child's potential development as assessed via supported performance, as a distinct cognitive characteristic.

Importantly, however, our work also extends Day et al.'s (1997) investigation as well as other seminal DA studies that examine DA's utility as a predictor of academic performance (e.g., Speece et al., 1990; Swanson & Howard, 2005) by assessing whether DA is a viable predictor of future (rather than concurrent) achievement. It also extends Spector's (1992) prediction of kindergarteners' future reading performance by considering how instruction affects relations among static and dynamic measures in forecasting school learning. In terms of whether DA is a viable predictor of future learning, our results provide support. We contrasted a full model of predictors, which included treatment plus six dimensions of pretreatment performance (language ability, nonverbal reasoning, attentive behavior, DA, calculations skill, and word-problem skill), against models that isolated static cognitive abilities (language ability, nonverbal reasoning, and attentive behavior), that isolated DA, and that isolated math skill (calculations and word problems). None of these contrasting, more parsimonious models fit the data as well as the full model. Therefore, although DA (along with treatment) was insufficient, it was necessary in accounting for the

data structure. This finding suggests that DA may serve an important role in predicting students' future learning. It also indicates that forecasting later academic performance creates variance for DA to capture. This may occur because upcoming learning may relate better with learning potential as indexed via DA than with static assessments that are determined in part by culture, socioeconomic, and previous learning opportunity. More specifically, these findings support a possible connection between algebraic cognition and word-problem skill, a possibility that should be pursued in future work, and indicate that novel academic content may provide a productive avenue for designing DAs in other academic domains.

With respect to how instruction affects relations among static and dynamic measures in forecasting actual school learning, our measurement models showed that two latent variables of outcome, near- and far-transfer, were necessary to account for the structure of students' posttreatment word-problem skill, and both dimensions of outcome were important for understanding how instruction affects the relations among static and dynamic measures in forecasting learning. Although all items on all five outcome measures were novel and none had been used for instruction, only treatment and pretreatment calculations skill accounted for learning on the latent outcome variable more closely aligned with treatment. By contrast, to forecast learning on word-problem measures more distally related to treatment, DA as well as pretreatment language ability and pretreatment word-problem skill were necessary.

That treatment forecasted near- but not far-transfer word-problem outcome is not surprising because randomized control trials (e.g., Fuchs et al., in press; Fuchs, Hamlett, & Powell, 2003) have, while demonstrating the efficacy of the validated word-problem treatment used in the present study, revealed stronger effect sizes for near-transfer word-problem outcome measures (e.g., 1.73–1.90; Fuchs et al., in press) than for far-transfer word-problem outcome measures (e.g., 0.36; Fuchs et al., in press). It is possible that with more comprehensive treatments that more fully address more generalized performance, the value of DA (as well as language ability and pretreatment word-problem skill) in predicting outcome would decrease, as the value of the treatment increases. However, effecting transfer to distal problems represents a formidable challenge in the area of math problem solving (Bransford & Schwartz, 1999; Cooper & Sweller, 1987; Mayer, Quilici, & Moreno, 1999). Moreover, we note that the validated intervention employed in the present study is theoretically rooted in schema theory that addresses transfer (e.g., Chi, Feltovich, & Glaser, 1981; Gick & Holyoake, 1980; Mayer, 1992; Quilici & Mayer, 1996) and has been shown to accomplish transfer more effectively than conventional math problem-solving instruction (Fuchs et al., 2003a). In addition, it is impossible to address all novel problem types within any given instructional program. Thus, the prediction of distal transfer, as reflected in the kinds of complex, real-world problem solving and high-stakes assessments used as distal measures in the present study, is important.

Results are relevant to the present education reform known as responsiveness-to-instruction (RTI). RTI is embedded in a multi-level prevention system, borrowed from the public health system. In a multilevel prevention system, general education constitutes primary prevention. Students who do not respond to this universal, core program enter secondary prevention. In most research, this

involves one or more rounds of small-group tutoring using a validated tutoring protocol. Students who do not respond to this more intensive secondary prevention program are understood to have demonstrated “unexpected failure” to validated instruction (to which most students respond). On this basis, unresponsive students are deemed appropriate for more intensive and individualized forms of instruction at the tertiary prevention level. In this way, RTI has two complementary purposes: (a) to identify at-risk students early and offer them intervention to prevent the onset of severe and often intractable deficits and (b) to identify students who are unresponsive to standard, validated instruction and who therefore require individualized instruction. In most RTI systems, these chronically unresponsive students are considered to have a learning disability (LD). In fact, the 2004 reauthorization of the Individuals with Disabilities Education Improvement Act of 2004 encourages RTI for LD identification as an alternative to the traditional identification procedure, which requires documentation of a discrepancy between IQ and school achievement and often delays identification until the intermediate grades (Vaughn & Fuchs, 2003).

Within RTI models, responsiveness to secondary prevention is considered the “test” for differentiating between two explanations for low achievement: inadequate instruction versus disability. If a child responds poorly to instruction that benefits most students, then this eliminates instructional quality as an explanation of poor learning and instead suggests disability. Although earlier identification/treatment of LD represents a potential advantage of RTI, conducting secondary preventive tutoring requires at least 10 weeks and, in some models, as many as 30 weeks. Present findings suggest that DA might serve an important function in predicting responsiveness to intervention, by forecasting distal, critical aspects of learning that are not highly relevant to the student’s proximal instructional needs. For example, within RTI reading models at first grade, secondary prevention focuses predominantly on the development of word-level skills and fluency because some work (e.g., Fuchs & Fuchs, 2005; Fuchs, Fuchs, Kazdan, & Allen, 1999) suggests that instruction to develop comprehension strategies when students are still struggling to identify words accurately and fluently may detract from reading development. Nonetheless, studies (Catts & Hogan, 2002; Compton, Fuchs, Fuchs, Elleman, & Gilbert, in press; Leach, Scarborough, & Rescorla, 2003; Lipka, Lesaux, & Siegel, 2006) show that a small but significant portion of the population experiences late-emerging reading disability, whereby their word-level and fluency skills develop typically, but serious comprehension deficits become evident at third or fourth grade. Yet, research has not reliably identified early predictors of late-emerging reading disability (Compton et al., in press). It is possible that DA might be used in first grade to forecast development of late-emerging reading disability. This would help teachers design appropriate instruction for this subset of students early on. In a different way, DA might be used productively within an RTI framework to help identify students who will ultimately, 10–30 weeks later, prove unresponsive to secondary prevention. If earlier identification, via DA, were possible, then more intensive and individualized forms of instruction could be introduced sooner, without children experiencing 10–30 weeks of additional failure.

Before closing, we note the small parameter-to-sample-size ratio in this study. Use of maximum likelihood estimation with small samples size has a tendency to produce chi-square estimates that

are too large. Thus, the decision for accepting or rejecting a particular model may vary as a function of sample size. In addition, sample size affects power in a predictable way, with smaller samples sizes having less power to detect differences between competing models using the chi-square statistic. Although our sample size was smaller than desirable, we did succeed in detecting significant differences using the  $\Delta\chi^2$  statistic across competing models. In addition, our reported Type 2 and Type 3 fit indices reflected adequate fit for our final measurement and structural models. These indices have been shown to be substantially less biased by sample size (Hu & Bentler, 1998). Therefore, we have some confidence that even with our sample size, the final models represent a good estimation of the relations among measures. Moreover, we ran a trimmed model, deleting paths with standardized coefficients of less than .10, which provided a similarly good fit with the data.

Nevertheless, the parameter-to-sample-size ratio remains a limitation of the present study, and future DA research employing structural equation modeling should incorporate larger samples. With this caution in mind, we conclude that findings provide an important basis for additional research assessing the utility of DA for indexing distal outcomes and for identifying students who require tertiary prevention in a more timely way. The present database indicates the potential utility of DA for predicting math problem-solving generalization across third grade. Parallel work, with larger samples, appears warranted to examine other aspects of academic learning.

## Appendix

### Instructional Scaffolding Levels for DA Skill A

For DA Skill A, during *Instructional Scaffolding Level 1*, the tester works problems for the student without explanation. The tester says, “I’m going to work some problems for you. Watch carefully while I work because I’ll ask you to do some more problems like these in a few minutes.” The tester then demonstrates three problems. Then the tester says, “Now you try to do some problems like these” and readministers the six-item test.

During *Instructional Scaffolding Level 2*, the tester explains the plus and equal signs mean and what the problem means/is asking. The tester says, “The plus sign tells us to add (*point*)”. And the problem asks us to figure out what number *x* stands for. What number (*point*) can we add to 6 (*point*) to make the total 8 (*point*)? *If correct*: “That’s right! 2 + 6 adds to 8. So the missing

number is 2. I write *x* equals 2 (*write*). Now let’s look at another problem.” *If incorrect*: “That’s not quite right. 2 plus 6 equals 8. So the missing number is 2. I write *x* equals 2 (*write*). Let’s try another problem. Now try to do this practice problem (*guide student using same procedure*).”

During *Instructional Scaffolding Level 3*, the tester elaborates on what *x* means, relating *x* to the “blank” that is used more commonly in the primary grades. The tester explains, “The blank (*point*) stands for the missing number, just like the *x* stands for the missing number in this problem (*point*). These two problems mean the same thing. They ask us to figure out what number *x*, or the blank, stands for. The problem asks, “What number (*point*) can we add to 6 (*point*) to make the total 14 (*point*)?” 6 plus what number equals 14?” *If correct*: “That’s right! 8 + 6 equals 14. So I write

8 in the blank. That tells me that the missing number,  $x$ , equals 8.”  
*If incorrect:* “That’s not quite right. 6 (*point*) plus 8 equals 14. So, the missing number is 8. So I write 8 in the blank. That tells me that the missing number,  $x$ , equals 8. After you figure out what the missing number is, you write the missing number like this:  $x = 8$ . We read the problem like this:  $6 + x = 14$ ;  $x = 8$ . Let’s try another problem, but this time you’ll try to do the work” (*guide student using same procedures*).

During *Instructional Scaffolding Level 4*, the tester provides the student with the min counting strategy for finding the missing number (i.e., starting with the larger addend and then counting up the second addend to derive the sum). The tester says, “What number (*point*) do we add to  $x$  (*point*)?” (Student: 7) “Yes, this problem tells us, 7 plus  $x$ . Put the number being added to  $x$ , 7, in your head. Now count up to the total, 13 (*point*). When I count up, I use my fingers until I reach the total (*point*), like this. I already have 7 in my head (*point to head*). I start counting up using the *next* number: 8 (*put up one finger*), 9 (*put up second finger, and continue putting up fingers for each subsequent number*), 10, 11, 12, 13. How many fingers am I holding up?” (Student: 6). “Yes, I have 6 fingers up. So,  $x$  equals 6. I know that 7 (*point*) + 6 (*write 6 above the x*) equals 13 (*point*). So, I know that  $x$  equals 6, and I write my answer like this:  $x = 6$ . You write the answer for me (*student writes*).” *If correct:* “That’s right! # + # equals #. So I write # in the blank. That tells me that the missing number,  $x$ , equals #.” *If incorrect:* “That’s not quite right. # (*point*) plus # equals #. So, the missing number is #. So I write # in the blank. That tells me that the missing number,  $x$ , equals #. Let’s try another one, but this time you’ll try to do it on your own” (*guide student using same procedures*).

During *Instructional Scaffolding Level 5*, the tester adds color coding to help the student discriminate the salient components of

the min strategy, thereby increasing the level of scaffolding with concreteness. The tester says, “This problem asks us to find what number  $x$  stands for. The problem asks, ‘What number (*point*) can we add to 3 (*point*) to make the total 5 (*point*)?’ What number (*point*) do we add to  $x$  (*point*)?” (Student: 3) “Yes, this problem tells us, 3 plus  $x$ . This number is written in green to help you remember to start counting here (*point*). Put the green number, 3 (*point*), in your head. Now count up to the total, 5 (*point*). What color is the total in this problem?” (Student: Red.) “Yes, the total is written in red to tell us when to stop counting up. We put the green number in our head. Then, we count up with our fingers until we reach the red total, like this. When I count up, I use my fingers until I reach the total (*point*). I already have the green 3 in my head (*point to head*). I start counting up using the *next* number: 4 (*put up one finger*), 5 (*put up second finger*). How many fingers am I holding up?” (Student: 2.) “Yes, I have 2 fingers up. So,  $x$  equals 2. I know that 3 (*point*) + 2 (*write 2 above the x*) equals 5 (*point*). I know that  $x$  equals 2, and I write my answer like this:  $x = 2$ . You write the answer for me (*student writes*).” *If correct:* “That’s right! # + # equal #. So I write # in the blank. That tells me that the missing number,  $x$ , equals #.” *If incorrect:* “That’s not quite right. # (*point*) plus # equals #. So, the missing number is #. So I write # in the blank. That tells me that the missing number,  $x$ , equals #. Let’s try another one, but this time you’ll try to do the work” (*guide student using same procedures*).

## Call for Nominations

The Publications and Communications (P&C) Board of the American Psychological Association has opened nominations for the editorships of **Developmental Psychology**, **Journal of Consulting and Clinical Psychology**, and **Psychological Review** for the years 2011–2016. Cynthia García Coll, PhD, Annette M. La Greca, PhD, and Keith Rayner, PhD, respectively, are the incumbent editors.

Candidates should be members of APA and should be available to start receiving manuscripts in early 2010 to prepare for issues published in 2011. Please note that the P&C Board encourages participation by members of underrepresented groups in the publication process and would particularly welcome such nominees. Self-nominations are also encouraged.

Search chairs have been appointed as follows:

- **Developmental Psychology**, Peter A. Ornstein, PhD, and Valerie Reyna, PhD
- **Journal of Consulting and Clinical Psychology**, Norman Abeles, PhD
- **Psychological Review**, David C. Funder, PhD, and Leah L. Light, PhD

Candidates should be nominated by accessing APA’s EditorQuest site on the Web. Using your Web browser, go to <http://editorquest.apa.org>. On the Home menu on the left, find “Guests.” Next, click on the link “Submit a Nomination,” enter your nominee’s information, and click “Submit.”

Prepared statements of one page or less in support of a nominee can also be submitted by e-mail to Emnet Tesfaye, P&C Board Search Liaison, at [etesfaye@apa.org](mailto:etesfaye@apa.org).

Deadline for accepting nominations is January 10, 2009, when reviews will begin.

# Catching Up or Falling Behind? Initial English Proficiency, Concentrated Poverty, and the Reading Growth of Language Minority Learners in the United States

Michael J. Kieffer  
Harvard University

This study contrasts growth trajectories in English reading for 2 groups of language minority (LM) learners—those who enter kindergarten with limited oral English proficiency and those who enter kindergarten proficient in oral English—with that of native English speakers. Fitting a multilevel model for change to longitudinal data on a nationally representative sample, this study examines students' growth trajectories from kindergarten through 5th grade. Three noteworthy findings emerge. First, LM learners entering kindergarten proficient in English have trajectories similar to those of native English speakers, but LM learners entering kindergarten with limited English have trajectories that diverge from those of native English speakers, yielding large differences in achievement by the 5th grade. Second, controlling for demographic risk factors, including socioeconomic status (SES), reduces the effect of initial English proficiency from large to moderate and yields differences that narrow over time. Finally, these differences depend on school poverty, with smaller differences evident among students in high-poverty schools than among students in low-poverty schools. Results emphasize the need for academic interventions for LM learners who enter school with limited English proficiency.

**Keywords:** reading development, second-language learners, achievement gaps, poverty, Early Childhood Longitudinal Study—Kindergarten Cohort

Cross-sectional studies have consistently found that students who come from homes in which a language other than English is spoken—referred to as language minority (LM) learners—have lower reading achievement in English than their native English-speaking peers (for a review, see August & Shanahan, 2006). However, few longitudinal studies have examined LM learners' growth trajectories in reading over time, particularly through the upper elementary school grades. Consequently, it is unclear to what extent these growth trajectories converge on, or diverge from, those of native English speakers.

The population of LM learners includes all students who have been exposed to a language other than English at home, whether they have limited English proficiency, are proficient in both languages, or are English dominant (August & Hakuta, 1997; August & Shanahan, 2006). At any given grade level, a subset of these learners will lack the English proficiency to gain full access to

mainstream instruction without support and thus be classified as English language learners or limited English proficient (LEP; August & Shanahan, 2006). Whereas LM learner status is conceptualized as a fixed characteristic that does not change over time, the English language learner and LEP labels are temporary classifications. Despite the recognition that these labels are temporary, much of the research that compares LM learners with native English speakers includes only those students classified as limited in proficiency at the time of the study. As a result, analyses of the achievement gaps between LM learners and native English speakers, such as those based on the National Assessment of Educational Progress results (e.g., National Center for Educational Statistics [NCES], 2007), present a biased picture of the achievement of the overall population of LM learners.

A preferable approach in developmental research has thus been to define the population by its time-invariant LM learner status (e.g. August & Hakuta, 1997; August & Shanahan, 2006). However, an overall comparison between the population of LM learners and the population of native English speakers may obscure qualitative differences within the heterogeneous group of LM learners. Of particular interest to developmental researchers is the extent to which differences among LM learners in initial English proficiency at the time of school entry predict differential growth in English reading. By sampling the entire population of LM learners and measuring their English language proficiency before formal schooling, a longitudinal analysis has the potential to examine the role of initial English language proficiency in later growth in English reading. Understanding this issue is fundamental to investigating how U.S. schools are meeting the instructional needs of this rapidly growing population.

---

The original collection of the ECLS-K data was funded by the National Center for Educational Statistics, U.S. Department of Education. This secondary analysis was funded in part by a Harvard University Presidential Fellowship and a Spencer Foundation Research Training Grant. I thank John B. Willett for his extensive methodological guidance and Nonie K. Lesaux and Catherine E. Snow for their valuable insights into the theoretical background and implications of this research. I also thank Kristen Bub, Mindy Munger, Young-Suk Kim, Gabrielle Rappolt-Schlichtmann, and Claire Vallotton for their helpful feedback on earlier versions of this article.

Correspondence concerning this article should be addressed to Michael J. Kieffer, Harvard Graduate School of Education, Harvard University, Larsen Hall 316, 14 Appian Way, Cambridge, MA 02128. E-mail: michael\_kieffer@gse.harvard.edu

## Examining English Reading Growth Among LM Learners

Although research in education and child development is often enhanced by the analysis of longitudinal data, analyses of growth over time are particularly essential to the study of LM learners. Cross-sectional comparisons of LM learners and native English speakers can suffer from cohort effects if the LM learners studied are only a subset of the population with an LEP label or if immigration patterns lead to differences between cohorts. Yet, the majority of studies that have modeled reading growth, as opposed to reading achievement, have been conducted with native English speakers (e.g., Compton, 2000; Francis, Shaywitz, Stuebing, Shaywitz, & Fletcher, 1996; Foorman, Francis, Novy, & Liberman, 1991; O'Malley, Francis, Foorman, Fletcher, & Swank, 2002; Swanson & Jerman, 2007) or have used large data sets that included LM learners without examining LM learner status (e.g., Chatterji, 2006).

Among the few longitudinal studies that have been conducted with LM learners, the majority have only followed participants until second or third grade (e.g., Chiappe, Siegel, & Wade-Woolley, 2002; Gerber, Jimenez, Leafsteadt, Villaruz, Richards, & English, 2004; Manis, Lindsey, & Bailey, 2004; Stuart, 2004; Swanson, Saez, & Gerber, 2006; Verhoeven, 1990, 2000). Only two studies, to my knowledge, have followed participants beyond the primary grades (Lesaux, Rupp, & Siegel, 2007; Reese, Garnier, Gallimore, & Goldenberg, 2000). Although informative about the nature of reading development, these studies provide limited information about how growth trajectories in English reading might differ between native English speakers and LM learners in the United States. Lesaux et al. (2007) conducted their study in a Canadian city in which LM learners were evenly distributed across neighborhoods and socioeconomic levels, thus limiting their ability to generalize their findings to areas in the United States in which poverty and LM status are confounded. Reese et al. (2000) examined the English reading achievement of Spanish-speaking LM learners without the benefit of a native English-speaking comparison group.

### Theoretical Framework: Two Hypotheses for LM Learners' Growth in English Reading

The theoretical framework of this research acknowledges the developmental nature of reading and the possibility that the determinants of reading achievement change over time (RAND Reading Study Group, 2002). There is a general consensus that LM learners start school at elevated risk for reading difficulties, especially LM learners who enter kindergarten with limited English proficiency (August & Shanahan, 2006; Snow, Burns, & Griffin, 1998). However, there is much less understanding about how this risk affects reading growth over the course of the elementary school years. This study examines two hypotheses that describe the English reading development of LM learners relative to native English speakers: a *differential skills* hypothesis that posits that the growth trajectories in reading of the two groups will diverge over time and a *developmental lag* hypothesis that posits that the growth trajectories will converge over time, such that LM learners eventually catch up with native English speakers.

The differential skills hypothesis draws theoretical support from models of reading that posit that the relative contributions of component skills to reading achievement change over time, such as

Chall's (1983) stages of reading development and the RAND Reading Study Group's (2002) conceptualization of reading comprehension. Put simply, these models hypothesize that different skills come into play in the act of reading at the different grade levels. Whereas word-reading skills play the central role in reading achievement in kindergarten through third grade (e.g., Adams, 1990; Perfetti, 1988), oral language proficiency and higher order comprehension processes play greater roles in reading achievement in Grade 4 and beyond (e.g., Anderson & Freebody, 1983; RAND Reading Study Group, 2002; Vellutino, Scanlon, Small, & Tansman, 1991). Moreover, compared with early reading skills, proficient reading comprehension in later grades is more dependent on a wide array of experiences (RAND Reading Study Group, 2002) and on the knowledge accumulated from students' exposure to print (Cunningham & Stanovich, 1997).

The empirical research on the English reading development of LM learners generally supports this hypothesis. In a recent review, the National Literacy Panel on Language Minority Children and Youth found that LM learners can achieve levels equal to those of native English speakers at the word-reading tasks that predominate in the early grades, but they have low achievement on the reading comprehension tasks that become central in the upper elementary grades (Lesaux, 2006). In particular, studies using a longitudinal design have found word-reading development of LM learners on par with that of native English speakers (e.g., Chiappe et al., 2002; Lesaux et al., 2007; Lesaux & Siegel, 2003; Manis, Lindsey, & Bailey, 2004) or have found small differences in word reading between the two groups that disappear over time (Verhoeven, 1990, 2000). However, each of these studies has also found deficiencies in one or more aspects of LM learners' oral language skills in English—such as their vocabulary, syntactic awareness, and verbal working memory—that may predict future difficulties in English reading comprehension.

On this basis, it is expected that the growth trajectories in English reading of LM learners and native English speakers will diverge over the elementary school years, as reading becomes less about decoding words fluently and more about integrating sophisticated vocabulary knowledge, higher order thinking skills, and rich content knowledge to comprehend difficult texts. It is further expected that this divergence will affect LM learners with different initial levels of English oral proficiency differently. It is likely that students who enter kindergarten with limited oral English proficiency fall behind native English speakers at a faster rate than do LM learners who enter kindergarten more proficient in English. Indeed, one longitudinal study of a group of Spanish-speaking LM learners (Reese et al., 2000) detected a strong relationship between initial English proficiency at kindergarten entry and English reading achievement in seventh grade.

Alternately, the developmental lag hypothesis argues that given sufficient time and exposure to English, the reading growth trajectories of LM learners will converge on those of their native English-speaking peers. Currently, this hypothesis has limited theoretical or empirical support, although there is evidence that some LM learners can catch up with the academic achievement of their native English-speaking peers when given an extended window of opportunity, sometimes as long as 10 years (e.g., Collier, 1989; Hakuta, Butler, & Witt, 2000). Contrary to this, an assumption that LM learners will catch up with their classmates quickly is the basis for many current instructional programs that serve these learners. Transitional bilingual and English-as-a-second-language programs

typically provide services to students for 1 to 3 years, after which they are expected to be ready for mainstream classroom instruction in English (Zehler et al., 2002). Such programs presume that LM learners' English reading development converges with that of native English speakers once students have had the time to develop oral English proficiency.

Thus, testing whether the differential skills or developmental lag hypothesis best describes the growth trajectories in English reading of LM learners is a developmental question that informs how educational programs to serve these learners are conceptualized, designed, and implemented. This study evaluates these two hypotheses using a developmental framework to analyze longitudinal data on English reading achievement between kindergarten and fifth grade from a nationally representative sample.

### Poverty and LM Learner Status

Reading research has identified several factors—in addition to initial English proficiency—that are associated with greater risk of reading difficulties, including a low-income family background, being a student of color, and attending a school with a high concentration of poverty, a high concentration of students of color, or both (for a review, see Snow et al., 1998). Because LM learners in the United States are more likely to be poor, to be students of color, and to attend highly segregated schools (Capps et al., 2005; Cosentino de Cohen, Deterding, & Chu Clewell, 2005), it is important to disentangle the effects of these risk factors from the effects of LM learner status.

In particular, the negative effects that accrue from living in poverty and attending a high-poverty school likely contribute to the low achievement of LM learners. The confounding of SES and LM learner status in many analyses of reading achievement, such as those based on National Assessment of Educational Progress scores, makes it difficult to determine whether the apparent effects of LM learner status are instead a result of influences related to poverty. Indeed, there is some evidence that differences between LM learners and native English speakers are minimal when the two groups are matched on SES. For instance, in a study conducted in a Canadian school district in which the SES of LM learners was equal to that of native English speakers, Lesaux et al. (2007) found that LM learners demonstrated growth trajectories in English reading from kindergarten to fourth grade that were indistinguishable from those of native English speakers.<sup>1</sup>

Although socioeconomic differences may explain some of the achievement differences between LM learners and their native English-speaking peers in the United States, it is unlikely that LM learners' status has no effect independent of its relationship with poverty. As described above, the deficiencies in English oral language consistently found among many LM learners likely constrain their English reading development, and such deficiencies are likely to be less common or less pronounced among native English speakers experiencing similar levels of poverty but exposed to greater amounts of oral English at home. Moreover, the effects of poverty may be greater for LM learners than for their classmates if their limited English proficiency prevents them from accessing educational resources meant to ameliorate the effects of poverty, such as Title I supplementary educational services. A common argument among advocates for improving the education of LM learners is that these learners have less access to educational

resources than their native English-speaking peers, even within the same high-poverty schools (Gándara, Rumberger, Maxwell-Jolly, & Callahan, 2003).

### Research Questions

The present study is a secondary analysis of multiwave data on a nationally representative sample of U.S. elementary school children from the Early Childhood Longitudinal Study—Kindergarten Cohort (ECLS-K) dataset. The purpose of the study is to describe the differential English reading development trajectories of three subpopulations of students: (a) native English speakers, (b) LM learners who enter kindergarten with initially limited English proficiency (LM-iLEP),<sup>2</sup> and (c) LM learners who enter kindergarten with initially full English proficiency (LM-iFEP). The analyses describe these trajectories both as they exist on average in the national population and as they differ by children's demographic background and schooling context. Three sets of research questions guide this study:

1. Do growth trajectories in English reading of LM learners diverge from those of native English speakers over the elementary school years, thus supporting the differential skills hypothesis? Among LM learners, is this divergence greater for students who are LM-iLEP compared with those who are LM-iFEP?
2. Do growth trajectories in English reading of LM learners (LM-iLEP and LM-iFEP) converge with those of native English speakers from similar demographic backgrounds attending demographically similar schools over the elementary school years?
3. Does the effect of selected student and/or school demographic risk factors vary as a function of LM learner status, such that LM learners are more vulnerable to the effects of these risk factors?

### Method

#### *Dataset*

This study uses data from the ECLS-K (Tourangeau, Lê, & Nord, 2005), a study conducted by NCES that examines the complex roles of school, home, and individual characteristics on students' academic and behavioral development over the school years. In conducting the ECLS-K, NCES used a multistage probability sampling design to select a cohort of students that was

<sup>1</sup> However, it is also worth noting that the district in which this study was conducted had a strong early literacy program, including early intervention efforts for students at risk for reading difficulties; although not explicitly focused on LM learners, such instructional efforts may have contributed to the equal success of these learners.

<sup>2</sup> Educators and researchers (e.g., August & Hakuta, 1997) have expressed objections to the term *LEP students* as a negative label with connotations of a permanent deficit. I agree with this objection and use LM-iLEP in this article solely to describe an initial condition rather than to describe children and use the convention of people-first language by using "students who were LM-iLEP" rather than "iLEP students."

nationally representative of students entering kindergarten in the 1998–1999 school year; as such, it includes children from a wide variety of socioeconomic, ethnic, and linguistic backgrounds attending a wide variety of public, private, and parochial schools. As described in detail in Tourangeau et al. (2005), NCES took major steps to minimize attrition and preserve the representativeness of the sample over time. As the only nationally representative longitudinal study designed to include school-age LM students, this dataset is well suited to addressing the research questions.

The analytic sample includes 17,385 students from the ECLS-K study who had one or more reading score; this sample includes all but 180 of the students from the original sample, preserving its representativeness.<sup>3</sup> Approximately 13% of the sample reported speaking a non-English language at home; roughly half of these were students classified as LM-iLEP in the fall of kindergarten. Students were then assessed longitudinally a maximum of six times in the fall of kindergarten, spring of kindergarten, fall of first grade (for a random subsample of students), spring of first grade, spring of third grade, and spring of fifth grade. The analyses incorporated baseline demographic and language data obtained in the fall of kindergarten and multiple waves of English reading achievement data obtained from spring of kindergarten through the spring of fifth grade. ECLS-K methodological reports provide detailed information on the data collection procedures (Tourangeau et al., 2005).

## Measures

*English reading achievement.* The outcome of interest is children's overall English reading achievement. It was assessed with an individually administered, two-stage reading test assembled by a panel of content experts using items from published standardized tests (Pollack, Atkins-Burnett, Najarian, & Rock, 2005). Drawing on and extending the National Assessment of Educational Progress framework, the test assessed basic reading skills (familiarity with print, recognition of letters, recognition of phonemes, and decoding), vocabulary, and five types of reading comprehension skills (initial understanding, developing interpretation, personal reflection and response, and developing a critical stance). The analyses used the number-right true scores scaled using item response theory as the outcome, as these scores were constructed to be vertically equatable across occasions of measurement. As reported in Pollack et al. (2005), estimates of internal consistency reliability for these scores were high (.93 to .96, depending on wave). In field testing, the reading scores had a high correlation (.83) with scores from the construct validation instrument, the Woodcock-McGrew-Werder Mini-Battery of Achievement; this cross-test correlation was higher than the cross-content correlations with the other ECLS-K cognitive measures (.73 with math and .72 with science), providing evidence for the validity of inferences about students' reading achievement based on these scores. Two limitations of the ECLS-K measures are worth noting. First, the lack of a commonly used standardized instrument makes it difficult to make direct comparisons between these scores and scores reported in other studies. Second, the reading achievement of all LM learners was assessed in English only, preventing the examination of reading abilities in students' native languages.

*Time.* Time was specified as the child's age in months, measured at each wave and centered on each student's age at the

testing date in the spring of fifth grade (CAGE). Thus, the intercept in the hypothesized individual growth trajectory in reading represents the student's true "final" reading status in the spring of fifth grade. This final-status specification was selected on the basis of a substantive interest in whether LM learners ultimately catch up with native English speakers by the end of the elementary school years; with this specification, the main effects of the predictors can be interpreted easily as the ultimate differences in reading achievement associated with these variables. The downside of this specification is that the effects of predictors on final rate of change and acceleration are more difficult to interpret; readers are thus provided with fitted growth plots and corresponding effect sizes to ease interpretation of differences in the shape of growth trajectories. Because CAGE was centered on each student's age, a second time-invariant control predictor was also included in the statistical models to represent each student's deviation in months of age from the sample median final age as well as interactions between this predictor and the linear and quadratic terms for CAGE. Details on this and other variable specifications are available from me.

*English language proficiency group.* The predictor for Research Question 1 was the students' time-invariant initial classification into one of three English language proficiency groups, based on their LM learner status and oral English proficiency at school entry: (a) native English speakers, (b) LM learners who were LM-iLEP, and (c) LM learners who were LM-iFEP. First, children were classified as LM learners or native English speakers on the basis of parental report in the fall of kindergarten (for approximately 90% of cases), in the spring of kindergarten (for approximately 8% of cases), or in the spring of first grade (for fewer than 2% of cases). Second, LM learners were classified as either LM-iLEP or LM-iFEP on the basis of whether their scores on the English Pre-Language Assessment Scales (Pre-K LAS; Duncan & DeAvila, 1998) at school entry (i.e., in the fall of kindergarten for more than 90% of children) fell above or below a cut-score established by the authors of the Pre-K LAS.<sup>4</sup> Note that this construct is a time-invariant classification, referring to students' LM learner status (i.e., LM or native English) and initial English language proficiency and should not be confused with students' concurrent English language proficiency, which would be expected to change over time. This categorical predictor consisted of two dummy variables representing LM-iLEP status and LM-iFEP status, with native English speakers specified as the

<sup>3</sup> These students were excluded because they did not have reading scores at any time point. Some were students with severe disabilities who were thereby excluded from all the cognitive measures, whereas others were LM learners who were excluded from testing in early rounds because of limited English proficiency and were then lost to follow-up in the third- and fifth-grade rounds (during which all students were tested regardless of English proficiency). Although it is therefore likely that these 180 students differ systematically from the original sample of 17,565, their small number indicates only a very small threat to the validity of generalizations to the population of U.S. school children who entered kindergarten in 1998.

<sup>4</sup> It is worth noting that the Spanish oral language proficiency of Spanish-speaking LM learners was also assessed at school entry. However, these scores are not included in the present analyses for two reasons. First, comparable scores were not available for students speaking other native languages. Second, the role of native language proficiency in second-language reading achievement is beyond the scope of the present investigation.

reference category (i.e., coded with a 0 for both LM-iLEP status and LM-iFEP status). Thus, the intercept can be interpreted as the predicted value for native English speakers.

*School-level and student-level demographic variables.* The student-level demographic variables included were native language background (Spanish or another language), ethnicity, and SES (represented by an ECLS-created composite of parents' education, occupation, and household income). School-level demographic variables included concentration of poverty (measured as the percentage of students receiving free or reduced-price lunch), concentration of students of color, and concentration of students with a school-based designation of LEP, each based on administrator reports. All student-level and school-level control predictors were declared time invariant; their values were fixed to the average value of the child's available values across the five occasions of data collection, with the exceptions of ethnicity and native language.

Preliminary analyses indicated that, as hypothesized, LM learner status was largely confounded with demographic risk factors. Table 1 displays the sample means of the demographic variables included, by English language proficiency group, along with the results of *t* tests of population equivalences in mean among the groups. The column on the far right indicates that when compared with native English speakers, LM learners were more likely to be Latino or Asian/Pacific Islander and tended to have lower SES (by approximately 0.60 standard deviation). On average, LM learners also attended schools with much higher concentrations of poverty and higher concentrations of both students of color and students designated as LEP than did native English speakers. It is worth noting within the population of LM learners the demographic differences between those who entered kindergarten proficient in English and those who entered with limited proficiency in English. The third column indicates that compared

with students in the LM-iLEP group, students in the LM-iFEP group were more likely to be Asian or Pacific Islander and were less likely to be Latino and tended to have higher SES (by more than .50 standard deviation). On average, students who were LM-iFEP attended schools lower in poverty, lower in concentrations of students of color, and lower in concentrations of students designated as LEP than did students who were LM-iLEP.

*Late qualifying.* There was variation in the age at which LM learners gained enough English proficiency to be administered the reading assessment. Students who did not pass the Pre-K LAS at each wave in kindergarten and first grade were excluded from taking the reading test, whereas those LM learners who passed the Pre-K LAS took the reading test in that round and in all subsequent rounds. In third and fifth grade, all students were assessed on the reading test regardless of English language proficiency. Thus, a simple estimate of the effect of LM-iLEP status may be positively biased by the systematic exclusion of the group of students who were the slowest to acquire English (and therefore also likely to be low in reading). Table 2 displays the frequencies and sample proportions of LM learners who were LM-iLEP and excluded from testing and the proportion who qualified at each wave of data collection. The exclusion of large proportions of students who were LM-iLEP in the early waves suggests that the potential bias may be substantial. To assess the effect of the exclusion of students who were LM-iLEP from reading testing in the early waves because of limited English proficiency, time-invariant dummy control predictors were included in some of the statistical models to identify the periods in which students were late-qualified for the reading test after being previously excluded (iLEP-QUALTIME2, iLEP-QUALTIME3, and iLEP-QUALTIME4).

Table 1

*Sample Means and Differences Between the Means of Selected Child- and School-Level Demographic Characteristics for Language Minority (LM) Learners Who Entered Kindergarten With Initially Full English Proficiency in English (LM-iFEP), LM Learners Who Entered Kindergarten With Initially Limited English Proficiency (LM-iLEP), and Native English Speakers*

Table 2  
Sample Frequencies and Proportions of Language Minority (LM) Learners Who Both Entered Kindergarten With Initially Limited English Proficiency (iLEP) and Qualified or Were Systematically Excluded From Reading Assessment in Each Wave of Data Collection

Wave	Cumulative frequency of students who were LM-iLEP & qualified	Proportion of students who were LM-iLEP and late qualified	Proportion of students who were LM-iLEP who were excluded
Time 0 (Fall, Kindergarten)	0	—	1.00
Time 1 (Spring, Kindergarten)	577	—	0.60
Time 2 (Fall, 1st grade)	646	0.05	0.55 <sup>a</sup>
Time 3 (Spring, 1st grade)	1,087	0.33	0.25
Time 4 (Spring, 3rd grade)	1,408	0.25	0.00
Time 5 (Spring, 5th grade)	1,408	—	0.00

<sup>a</sup> This is an extrapolation based on the proportion of the students who were not qualified to take the test in this round had they participated in it, not the actual proportion excluded in this subsample. The frequency of students who qualified does not match the frequency of reading scores for students who were LM-iLEP because many students theoretically qualified for the reading test but did not participate in later waves of the study for other reasons.

Data Analysis

To address the research questions, a taxonomy of multilevel models for change was fitted in the person-period dataset that contained the longitudinal data on all sampled children, using STATA XT MIXED with maximum likelihood estimation. The multilevel model for change provides a powerful tool for addressing questions concerning systematic interindividual differences in change over time in longitudinal data (Singer & Willett, 2003). Preliminary inspection of empirical growth plots of each child's reading achievement as a function of age suggested that a quadratic growth specification was the most appropriate for representing the individual growth trajectories in reading. Thus, the multilevel model for change hypothesized to address the first research question, expressed in composite form, was

$$READING_{ij} = \left( \begin{array}{l} \gamma_{00} + \gamma_{10}CAGE_{ij} \\ + \gamma_{20}CAGE_{ij}^2 + \gamma_{01}CFINALAGE_i \\ + \gamma_{11}CFINALAGE_i \times CAGE_{ij} \\ + \gamma_{21}CFINALAGE_i \times CAGE_{ij}^2 \\ + \gamma_{02}ILEP_i + \gamma_{12}ILEP \times CAGE_{ij} \\ + \gamma_{22}ILEP \times CAGE_{ij}^2 \\ + \gamma_{03}IFEP_i + \gamma_{13}IFEP \times CAGE_{ij} \\ + \gamma_{23}IFEP \times CAGE_{ij}^2 \end{array} \right) + \zeta_{0i} + \zeta_{1i} \times CAGE + \varepsilon_{ij}$$

where  $\varepsilon_{ij} \sim N(0, \sigma_\varepsilon^2)$  and  $\begin{bmatrix} \zeta_{0i} \\ \zeta_{1i} \end{bmatrix} \sim N\left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} \sigma_0^2 & \sigma_{01} \\ \sigma_{10} & \sigma_1^2 \end{bmatrix}\right)$

where parameter  $\gamma_{00}$  represented the population average true final (spring of 5th grade) status, parameter  $\gamma_{10}$  represented the population average true final instantaneous slope, and parameter  $\gamma_{20}$  represented the population average true acceleration. Parameters  $\gamma_{01}$ ,  $\gamma_{11}$ , and  $\gamma_{21}$  represented the effects of variation in students' age at the final date of testing on the final status, final instantaneous slope, and acceleration. Parameters  $\gamma_{02}$  and  $\gamma_{03}$  represented the effects on final achievement of LM-iLEP and LM-iFEP status, respectively. Parameters  $\gamma_{12}$  and  $\gamma_{13}$  represented the effects on final rate of growth of LM-iLEP and LM-iFEP status, respectively. Parameters  $\gamma_{22}$  and  $\gamma_{23}$  represented the effects on acceleration of LM-iLEP and LM-iFEP status, respectively. The random effect  $\varepsilon_{ij}$

was a Level 1 residual for child  $i$  at time  $j$  and was assumed to be drawn from a normal distribution with mean of 0 and unknown variance  $\sigma_\varepsilon^2$ . Random effects  $\zeta_{0i}$  and  $\zeta_{1i}$  represented Level 2 residuals for intercept and slope, respectively. They were hypothesized to be drawn from a multivariate normal distribution with a mean vector of zero, unknown variances  $\sigma_0^2$  and  $\sigma_1^2$ , and unknown covariance  $\sigma_{01}$ . Attempts to include a random effect for the acceleration term created convergence problems, leading to the decision to fix this effect across individuals.

The hypothesized multilevel models to address the second and third research questions were similar to this model, with the addition of terms representing the effects of the student-level and school-level demographic variables described above on final status, final rate of growth, and acceleration, as well as the interactions between these variables and LM-iLEP and LM-iFEP status. Following the recommendation of Singer and Willett (2003), the likelihood ratio test was the primary index used to compare the goodness of fit of successive models. The Akaike information criterion and Bayesian information criterion were also estimated and compared; changes in both of these indices corroborated the conclusion of the likelihood ratio test in all but one case, in which the conclusion indicated by the likelihood ratio test and Akaike information criterion was selected over that indicated by the Bayesian information criterion.

Missing Data

Some data were missing in the ECLS dataset both at Level 1 (within child) and at Level 2 (between child), with the most substantial data missing in the school-level demographic variables at each wave and in the outcome at the fifth-grade wave. Several strategies were used to make use of all legitimate, available information without imputing values or excluding cases (either of which would have imposed more stringent assumptions on the model). First, as recommended by Singer and Willett (2003), any child contributing one or more waves of reading score to the person-period dataset was included in the analyses and contributed the available multiwave information they provided to the Level 1 estimation, whereas missing waves of reading scores were simply not included in the person-period dataset or analyses. Second, the

systematic missingness in Level 1 data due to the exclusion of students with limited English proficiency from the reading test in early waves was taken into account explicitly through the inclusion of the late-qualifying variables described above. Third, by specifying the control variables as time invariant and fixing these to the average of the available values across the five waves of data collection, any student who had survey data from one or more waves was able to have an empirically based value for these variables. Following this decision, only 1% of students lacked data on a student-level control variable, and 18% of students lacked data on a school-level control variable. Fourth, Cohen's (2003) model-based approach was used to include these remaining children; following this approach, arbitrary values ( $-9$ ) were assigned to any missing value for any control predictor, and additional dummy predictors were created and included to accompany these predictors to indicate which values were missing and replaced by placeholders. Resulting parameter estimates were thus the product of all available nonmissing information, and values did not need to be imputed on the basis of some specified set of predictors.

These four strategies allowed for the inclusion of 17,385 students, constituting more than 99% of the original ECLS-K participants, and 62,992 observations, constituting 85% of the observations (i.e., reading scores) that would be possible if there was no attrition or missing waves of outcome data. Supplemental analyses indicated that the absence of observations was in large because of the late qualifying of LM learners described above and to students moving between elementary schools (details are available from me). Regarding the latter concern, NCES followed only a subsample of 50% of students who moved between schools, selected at random.<sup>5</sup> This random selection ensured that there were no systematic differences between the movers with data and those who were missing data.

### *Accounting for the Complex Sampling Design of the ECLS-K*

In generalizing to the population of U.S. students who entered kindergarten in 1998, two aspects of the ECLS-K complex sample survey design warranted attention. First, to ensure adequate sample size in making comparisons, ECLS-K oversampled selected groups of children. In the base year, this included children who were Asian or Pacific Islander and children who attended private schools. In subsequent years, LM learners who changed schools were also oversampled, as compared with native English speakers who changed schools. Given the difficulties of incorporating details of the complex survey sample design into multilevel analyses with current statistical software, oversampling was accounted for by including predictors in the models that represented the dimensions on which the oversampling occurred (i.e., ethnicity, school type, and language minority learner status).

Second, ECLS-K used a multistage probability sampling design in which the primary sampling units (PSUs) were geographic areas consisting of counties or groups of counties, the second-stage units were schools, and the third-stage units were students within schools (Tourangeau et al., 2005). Accounting for this multistage sampling design while simultaneously fitting an appropriate multilevel model for change provided technical challenges that are not yet fully met by the statistical software currently available. The

STATA software package currently allows the fitting of multilevel models with relatively simple error structure while stipulating the PSUs (using the XTREG command and generalized least squares estimation) or the fitting of multilevel models with more complicated error structures without stipulating the PSUs (using the XTMIXED command and maximum likelihood estimation), but not both at the same time. Therefore, two parallel sets of analyses were conducted, in which first a taxonomy of multilevel models for change was fitted with the error structure described above but without accounting for the PSUs, using XTMIXED, and then selected models from this taxonomy were refitted using a simplified error structure (i.e., a multilevel model with random intercepts only), but accounting for the PSUs, using XTREG.

## Results

The findings for each of the three research questions are presented below. The first section presents results for models that compared the growth trajectories in English reading of LM learners and native English speakers without taking into account SES, race, or school demographics. This analysis provided the description of average achievement differences as they actually existed in U.S. schools. The second section presents results for models that took into account the demographic predictors of child ethnicity, child SES, school concentration of poverty, and school concentration of students of color. The magnitudes of these predictors were evaluated, along with the impact of including these predictors on the magnitudes of the effects of LM learner status. The third section presents results for a final model that included these effects and an interaction between LM learner status and school-level poverty.

For ease of interpretation, fitted growth trajectories were estimated for prototypical cases and displayed in graphical form, and effect sizes were estimated for differences in the elevation of these trajectories between LM learners and native English speakers at kindergarten, third grade, and fifth grade. Using effect sizes provides a standardized metric for assessing the magnitude of these differences and allows one to compare them against Cohen's (1992) conventions in which an effect size of .2 indicates a small effect, .5 indicates a medium effect, and .7 indicates a large effect. Comparing effect sizes is also preferable to evaluating the statistical significance of the parameter estimates alone; given the large sample size and its high statistical power, even very small effects with little practical importance can be statistically significant. Additionally, it is worth noting that all models were fitted using the complete dataset. Thus, the population described included students from diverse ethnic, linguistic, and socioeconomic backgrounds who attended U.S. schools. For the purposes of displaying fitted growth trajectories, all control variables had to be temporarily set to some prototypical values, thus the trajectories displayed were for Latino students with average SES who attended high- and low-poverty public schools with an average concentration of students of color. However, readers should bear in mind that analyses included data from all students and thus findings are not limited to this subpopulation.

<sup>5</sup> Language minority learners who moved schools were followed at a 100% rate.

Research Question 1: Many LM Learners Are Falling Far Behind the National Average

The first research question investigated the differential growth trajectories in English reading of LM learners and native English speakers. The findings indicated that LM learners who entered school with limited English proficiency had growth trajectories in reading that unfolded at substantially lower elevations than those of native English speakers throughout the elementary school years, but that LM learners who entered school proficient in English had growth trajectories in reading that were largely indistinguishable from those of native English speakers.

Table 3 displays a taxonomy of fitted multilevel models for change obtained in these analyses. The unconditional growth model, labeled *Model 1* in the table, indicated that as expected, a quadratic specification of reading achievement as a function of age described the curvilinear shape of reading development over time. On average, children’s reading achievement tended to increase with age ( $\hat{\gamma}_{10} = 0.477, p < .001$ ), but at a decelerating rate ( $\hat{\gamma}_{20} = -0.020, p < .001$ ).

Model 2 assessed the impact of LM-iLEP and LM-iFEP status on students’ fifth-grade reading status, final rate of growth, and acceleration in reading achievement, thus provid-

Table 3  
Taxonomy of Fitted Multilevel Models for Change in Which Reading Achievement Is a Quadratic Function of the Child’s Age, English Language Proficiency Group (LM-iLEP and LM-iFEP Compared With the Reference Category, Native English) and Late Qualification for the Reading Assessment Because of Limited English Proficiency (N = 17,385)

\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

ing a preliminary answer to the first research question. In this model, and in later models, the reference category was native English speakers; thus, the coefficients for the effects of LM-iLEP and LM-iFEP can be interpreted as the difference between these groups and native English speakers. Compared with native speakers, students who were LM-iLEP had a substantially lower fifth-grade status ( $\hat{\gamma}_{02} = -19.571, p < .0001$ ), a higher final rate of growth ( $\hat{\gamma}_{12} = 0.194, p < .0001$ ), and a rate of acceleration that was slightly but significantly higher ( $\hat{\gamma}_{22} = 0.006, p < .0001$ ). Students who were LM-iFEP did not differ from native English speakers in their fifth-grade status ( $p = .562$ ), their final rate of growth ( $p = .749$ ), or their rate of acceleration ( $p = .454$ ). When the complex survey design was taken into account by refitting the multilevel models with a simplified error structure and accounting for the PSUs using GLS estimation, each of these findings was found to be robust—the magnitudes of the effects were essentially the same, and there were no differences in the statistical inference.

As noted earlier, these estimates of the effect of LM-iLEP may be positively biased by the systematic exclusion of many students with low English proficiency from taking the reading test in Waves 1 through 3. As anticipated, accounting for the exclusion of these

students' scores in the early waves did in fact have an impact on the magnitudes of these estimates of the differences in trajectories. Model 3 in Table 3 displays a fitted multilevel model for change that included the set of dichotomous control predictors that distinguished the late qualifying of students who were LM-iLEP in each round (predictors iLEP-QUALTIME2, iLEP-QUALTIME3, and iLEP-QUALTIME4). In this model, likelihood ratio tests confirmed that the set of predictors describing late qualifying simultaneously predicted final status ( $p < .0001$ ), final rate of change ( $p < .0001$ ), and acceleration ( $p = .0082$ ). Given the inclusion of these variables, readers are cautioned in interpreting the parameter estimate for LM-iLEP in Models 3 to 6; in each of these models, this estimate refers to the effect of LM-iLEP status for only those students who were LM-iLEP and qualified for reading testing by the spring of kindergarten. A better interpretation of the effect of LM-iLEP status can be gained by looking across the parameter estimates for LM-iLEP, iLEP-QUALTIME2, iLEP-QUALTIME3, and iLEP-QUALTIME4 or by interpreting the fitted growth trajectories described below.

To provide insight into these findings, Figure 1 displays fitted growth trajectories in reading for native English speakers, for students who were LM-iFEP, and for students who were LM-iLEP

Figure 1. Fitted growth trajectories in reading for native English speakers, language minority learners who entered kindergarten with initially full English proficiency (LM-iFEP), and language minority learners who entered kindergarten with initially limited English proficiency (LM-iLEP) and late qualified for the reading test in each round ( $N = 17,385$ ). IRT = item response theory.

and qualified to take the test at each round. First, comparing the solid and dotted fitted trajectories at the top of the figure, notice that the predicted reading growths of native English speakers and of LM learners who entered kindergarten proficient in English are largely indistinguishable across the elementary school years.

Second, comparing the solid fitted trajectory with the thickly dashed fitted trajectories below reveals that LM learners who entered kindergarten with limited English proficiency had large and persistent gaps in English reading achievement compared with native English speakers throughout the elementary school years. The gray dotted line represents a weighted average of the growth trajectories in reading of the LM-iLEP groups that qualified for the reading test at different times; as such, it provides a single summary of what the average reading trajectory for students who were LM-iLEP could have looked like if all students had been included in the reading assessment from the spring of kindergarten. Comparing this weighted average fitted trajectory with the solid line that represents the average fitted reading trajectory for native English speakers reveals that the predicted gap in achievement between these groups increased between kindergarten and third grade, but then remained relatively stable between third and fifth grade.

Third, a comparison among the four different dashed fitted growth trajectories in reading shows that the excluded students were systematically lower in English reading achievement than other students who were LM-iLEP but assessed at every wave. The elevations of the fitted trajectories for each of the late-qualifying groups fell beneath those of the students who were LM-iLEP but qualified at Time 1 to take the reading test, substantially so in the

case of students who qualified at Time 3 or Time 4. The lowest achieving group consisted of those LM learners who did not acquire enough English by the end of first grade to take the reading test, as represented by the lowest dashed line on Figure 1; their predicted achievement in the spring of fifth grade was more than 29 item response theory scale score points (or approximately 1.25 standard deviation) below that of native English speakers. These students, who made up roughly 25% of the students who were LM-iLEP, may have been qualitatively different from the other two groups of late qualifiers. Technically, they never met the standard for English proficiency to take the reading test in first grade, but rather “qualified” for the reading test by virtue of an administrative decision to test all students in reading in third grade without first screening their English proficiency; although it is likely that many of them would have met the English proficiency standard in third grade, these data do not allow us to know what proportion of them would not have or to model how this might have predicted their growth.

Overall, when compared with native English speakers, students who were LM-iLEP, whether included or not in testing in early rounds, demonstrated fitted growth trajectories in English reading that were substantially lower in elevation and that diverged substantially between kindergarten and third grade. These differences persisted into fifth grade, but did not increase. To interpret the magnitude of these effects, the top half of Table 4 provides effect sizes for the fitted effects of LM-iLEP and LM-iFEP status (i.e., the vertical separation between the trajectories of these learners and those of native English speakers) for the spring of kindergar-

Table 4  
*Predicted Effect Sizes in Reading Achievement for LM Learners Who Entered Kindergarten With Initially Full English Proficiency (iFEP) and LM Learners Who Entered Kindergarten With Initially Limited English Proficiency (iLEP) as Compared With Native English Speakers (N = 17,385)*

Model		Effect size (Cohen's <i>d</i> )		
Model 2				
Effect of LM-iFEP				
Spring, Kindergarten			0.01	
Spring, 3rd grade			-0.03	
Spring, 5th grade			-0.03	
Effect of LM-iLEP				
Spring, Kindergarten			-0.71	
Spring, 3rd grade			-0.83	
Spring, 5th grade			-0.84	
Model 3	Highest estimate	Lowest estimate	Weighted average	
Effect of LM-iLEP				
Spring, Kindergarten		—	-0.34	-0.63
Spring, 3rd grade		-1.30	-0.48	-0.82
Spring, 5th grade		-1.33	-0.43	-0.83
Model 6 (in medium-poverty schools)				
Effect of LM-iLEP				
Spring, Kindergarten		—	-0.32	-0.57
Spring, 3rd grade		-0.77	-0.21	-0.44
Spring, 5th grade		-0.74	-0.11	-0.39

*Note.* In each model, the highest estimate of the gap between native speakers and the LM-iLEP group comes from those students who failed to pass the English proficiency test in the spring of first grade and therefore did not take the reading test until third grade, whereas the lowest estimate of the gap comes from those who passed the English proficiency test by the spring of kindergarten. The estimates from Model 6 were fitted for Latino children of average socioeconomic status who attended public schools of average concentration of poverty and average concentration of students of color.

ten, the spring of third grade, and the spring of fifth grade, based on Model 2. Because the difference in elevation between the trajectories of native English speakers and students who were LM-iLEP varied by when they qualified for the reading test, Table 4 also provides a range of estimated effect sizes for LM-iLEP. These include the lowest estimates (for students who were LM-iLEP and qualified at Time 1), the highest estimates (for students who were LM-iLEP and qualified at Time 4), and an average of estimated effect sizes, weighted by the proportions of students who were LM-iLEP and qualified in each round.

Consistent with the previous interpretation of the fitted growth trajectories, comparison of these effect sizes indicated on one hand that the English reading achievement of LM learners who entered kindergarten proficient in English differed slightly, if at all, from that of native English speakers in the elementary school grades. On the other hand, LM learners who entered kindergarten with limited English proficiency had medium-sized deficiencies in English reading achievement at the end of kindergarten that became large in the early elementary years and maintained thereafter.

### *Research Question 2: LM Learners Are Catching Up to Their Classmates*

My second research question asked whether the detected pattern of widening gaps in English reading achievement holds when LM learners are compared with native English speakers from similar demographic backgrounds who attended demographically similar schools. The findings indicate that controlling for these demographic characteristics led to fitted growth trajectories in reading for LM learners and native English speakers that were much more similar than those fitted without taking the demographic characteristics into account. Controlling for demographic factors also yielded fitted growth trajectories for the three groups that converged over the elementary school years. Table 5 lists three fitted multilevel models for change that illustrate the key findings concerning the effects of these demographic characteristics.

In Model 4, child-level demographic controls were statistically significant predictors of reading achievement. As one would expect, both children's ethnicity and SES affected the final status, final rate of change, and rate of acceleration of their fitted growth trajectories in reading (all  $p$ s < .05), with students of color and students from lower socioeconomic backgrounds having predicted growth trajectories unfolding at a substantially lower elevation. However, no feature of the growth trajectory—final status, final rate of change, and acceleration—was affected by whether the child spoke Spanish at home (all  $p$ s > .1540), once the child's ethnicity and SES had been taken into account. Although we might have expected that the effect of English language proficiency group would have differed for students of different ethnicities, level of SES, or native language, no significant interactions were found among these predictors.

In Model 5, the school-level demographic characteristics—concentration of poverty, concentration of students of color, and concentration of students designated as LEP—were investigated. Among these school-level predictors, concentration of poverty had the largest effects on students' growth trajectories in reading, specifically a substantial negative impact on predicted fifth-grade status (−.09 standard deviation for every additional 25 percentage points of students receiving free or reduced-price lunch;  $p$  < .001)

and statistically significant, but small, positive effects on final rate of growth ( $p$  = .005) and rate of acceleration ( $p$  < .001). Once the school's concentration of poverty was taken into account, the concentration of students of color did not have a significant effect on final status ( $p$  = .085), but did have significant, if small, positive impacts on the final rate of change ( $p$  = .012) and acceleration ( $p$  < .001). The school's concentration of students designated as LEP did not have a significant impact on any aspect of students' growth trajectories once other school demographics were taken into account.

As shown in Table 5, the estimated effects of LM-iLEP and LM-iFEP status on the fitted growth trajectories in reading were changed by the inclusion of the student-level and school-level demographics. The parameter estimate for the effect of LM-iFEP on final status became positive and statistically significant; LM learners who entered school proficient in English were predicted to be .13 standard deviation higher in reading by fifth grade compared to native English speakers of the same ethnicity and SES who attended schools with the same concentration of poverty and students of color ( $p$  = .004). The coefficient for the effect of LM-iLEP on final status was no longer significant, indicating that LM learners who entered school with limited English and qualified for the reading test by the spring of kindergarten had fifth-grade reading achievement that was no different from that of native English speakers with the same demographic risk factors. However, the coefficients for the effect of iLEP-QUALTIME3 and iLEP-QUALTIME4 on final status continued to be negative, large, and significant after accounting for school demographics, indicating that students who were LM-iLEP and excluded from early reading testing (making up 55% of all students who were LM-iLEP) had fifth-grade reading achievement that was substantially lower than that of native English speakers with similar demographic risk factors.

In sum, the findings for Research Question 2 indicated that controlling for the confounding influence of demographic risk factors led to a substantial change in the observed achievement differences between LM learners and native English speakers. LM learners who entered school proficient in English had growth trajectories that were higher in elevation than those of their demographically similar peers who attended similar schools, whereas LM learners who entered school with limited English had trajectories that were only moderately lower in elevation than those of their demographically similar peers who attended similar schools.

### *Research Question 3: The Interaction Between LM Learner Status and School Poverty*

The third research question focused on the potential moderating impact of LM learner status on the effects of demographic risk factors on English reading achievement. To address this question, two-way statistical interactions between variables for LM learner status and the demographic predictors were included in the multilevel models for change. Among the several two-way interactions tested, only the interaction between school poverty and LM learner status had a statistically significant effect on reading achievement. In the final model, Model 6, the interaction between LM learner status and school poverty had a significant effect on final status ( $p$  = .0331), final rate of change ( $p$  = .0319), and acceleration ( $p$  = .0252). This finding indicated that among students of

*Note.* Each model also included centered final age as a predictor of final status, final rate of change, and acceleration. Child controls not shown included child-level socioeconomic status and ethnicity. School controls not shown included concentration of students of color and type of school (public, private—Catholic, private—religious, and private—other). Free and reduced lunch was centered at the sample mean. Therefore, the main effects of LM-iLEP and LM-iFEP in Models 6 and 6a can be interpreted as the effects of these variables in a school with an average concentration of poverty. LM = language minority; LM-iLEP = LM learners entered kindergarten with initially limited English proficiency; LM-iFEP = LM learners who entered kindergarten with initially full English proficiency; PSU = primary sampling units; QUALTIME2 = qualified at Time 2 to take the reading test; QUALTIME3 = qualified at Time 3 to take the reading test; QUALTIME4 = qualified at Time 4 to take the reading test; FRLUNCH = free or reduced-price lunch.

similar demographic backgrounds, the gap in reading achievement between students who were LM-iLEP and native English speakers was smaller among students in high-poverty schools than was the corresponding gap among students in low-poverty schools. Students who were LM-iFEP and attended high-poverty schools had fitted growth trajectories that were significantly higher in elevation than those of native English speakers in such schools, whereas these learners who attended low-poverty schools had fitted growth

Figure 2. Fitted growth trajectories in reading for native English speakers, language minority learners who entered kindergarten with initially full English proficiency (LM-iFEP), language minority learners who entered kindergarten with initially limited English proficiency (LM-iLEP), who attend high-poverty and low-poverty schools, fitted for Latino children of average socioeconomic status attending public schools of average concentration of students of color ( $N = 17,385$ ). IRT = item response theory.

trajectories that were essentially equivalent to those of their native English speakers after controlling for individual demographics.

The two panels of Figure 2 display fitted growth trajectories in reading for students who attended low-poverty schools (in which 25% of students receive free or reduced-price lunch) and high-poverty schools (in which 75% of students receive free or reduced-price lunch). In both panels, the fitted trajectory of LM learners who were iLEP was a composite of the fitted trajectories of

students who were LM-iLEP, weighted by the proportion that qualified for the reading test in each round. Note that the fitted trajectories, and the effect sizes that follow, were for Latino students of average SES who attended public schools with an average concentration of students of color; given the interactions between age and these control variables in the model, these would be slightly different for a comparison involving prototypical cases with different values for the control variables. Table 6 provides the

Table 6

*Predicted Effect Sizes in Reading Achievement for Language Minority (LM) Learners Who Entered Kindergarten Proficient in English (iFEP) and LM Learners Who Entered Kindergarten With Limited English (iLEP) as Compared With Native English Speakers in High- and Low-Poverty Schools ( $N = 17,385$ )*

English language proficiency group	Effect size (Cohen's $d$ )			
	Low-poverty school		High-poverty school	
LM-iFEP				
Spring, Kindergarten	0.02		-0.09	
Spring, 3rd grade	0.07		0.16	
Spring, 5th grade	0.05		0.20	
LM-iLEP (weighted average)				
Spring, Kindergarten	-0.67		-0.41	
Spring, 3rd grade	-0.54		-0.29	
Spring, 5th grade	-0.45		-0.30	
LM-iLEP (by late qualifying)	Low estimate	High estimate	Low estimate	High estimate
Spring, Kindergarten	-0.42	—	-0.17	—
Spring, 3rd grade	-0.31	-0.88	-0.05	-0.63
Spring, 5th grade	-0.17	-0.83	-0.01	-0.67

Note. Each effect size was based on a fitted difference in the elevation of growth trajectories, fitted for Latino students of average socio-economic status who attended public schools with an average concentration of students of color. LM = language minority; LM-iLEP = LM learners entered kindergarten with initially limited English proficiency; LM-iFEP = LM learners who entered kindergarten with initially full English proficiency.

estimated differences, expressed as effect sizes, between native English speakers, LM learners who were iLEP, and LM learners who were iFEP in the spring of kindergarten, the spring of 3rd grade, and the spring of 5th grade.

Comparing the two panels of Figure 2 reveals that the differences between the English reading development of LM learners and that of native English speakers largely depended on the concentration of poverty in the schools they attended, as well as on the LM learners' initial proficiency in English. On one hand, among students who consistently attended low-poverty schools, the growth trajectories in reading of LM learners who entered kindergarten with limited English started lower and diverged more substantially from those of native English speakers with similar demographics, yielding moderate to large differences in fifth-grade achievement (with a weighted average effect size of .45). On the other hand, for students who attended high-poverty schools, the growth trajectories in reading for all students were lower in elevation (compared with those in low-poverty schools), but the differences between native English speakers and LM learners who were iLEP were substantially reduced (with an average effect size of .30 in fifth grade). For LM learners entering school proficient in English, the picture was quite different; in low-poverty schools, their trajectories had largely the same shape and elevation as those of native English speakers, but in high-poverty schools, their growth trajectories began at similar levels but diverged positively, yielding levels of reading achievement by fifth grade that were approximately .20 standard deviation higher.

Another way of interpreting this interaction is to say that differences in the growth trajectories in reading associated with attending schools of varying concentrations of poverty differed by students' English language proficiency group. Table 7 presents effect sizes for the predicted difference in reading achievement between students who attended high- and low-poverty schools over time by English language proficiency groups. Whereas stable and noteworthy differences existed between native English speakers who attended low- and high-poverty schools (between .16 standard deviation in kindergarten and .21 standard deviation in third grade), much smaller differences existed for students who were LM-iLEP and attended low- and high-poverty schools (rang-

ing from a positive difference of .10 standard deviation favoring students who attended high-poverty schools in kindergarten to a negative difference of .04 standard deviation favoring students who attended low-poverty schools by fifth grade). The pattern for LM learners who entered kindergarten proficient in English was even more striking. The association between school poverty and reading achievement diminished substantially over time for these learners. In kindergarten, students who were LM-iFEP and attended high-poverty schools had reading scores that were .27 standard deviation lower than those in low-poverty schools (as might have been expected), but this difference narrowed to .12 standard deviation by third grade and to .04 standard deviation by fifth grade.

Model 6b in Table 5 displays a version of the final model that accounted for the complex survey design while incorporating a simplified error structure. A comparison of Models 6 and 6b indicates that the magnitudes of the parameter estimates were largely similar whether or not the complex sampling design was taken into account. However, the two models did produce different results regarding the statistical significance of some small effects; most notably, Model 6b, in contrast to Model 6, indicated that students who were iLEP but qualified for the reading test by the end of kindergarten were significantly lower in fifth-grade status when compared with their native English-speaking counterparts of the same ethnicity and SES who attended schools of average SES. Nonetheless, these effect sizes were very similar in both specifications (−.11 and −.12), are considered small by the conventions of Cohen (1992), and have little practical importance, especially when compared with the much more substantial effects for students who were iLEP and qualified for testing later. Thus, the central findings were largely robust across these two methods of estimating effects.

Discussion

By examining language proficiency and English reading growth, this study provides several insights into our understanding of the reading development of LM learners. The first key finding is that the differences in levels of English reading across time between LM learners and native English speakers looked dramatically different when LM learners were disaggregated by initial English proficiency. LM learners who entered kindergarten proficient in oral English had substantial success in developing reading skills, whereas LM learners who entered kindergarten with LEP struggled throughout the elementary school years. The second key finding is that the answer to whether LM learners who entered kindergarten with LEP narrowed the gap over time depended on the group with which one compared their English reading achievement. Controlling for demographic risk factors, most notably the large effect of SES, the magnitude of the effect of initial English proficiency was reduced from large to moderate. Moreover, although the average growth trajectory in reading of students who were LM-iLEP diverged from the national average for native English speakers between kindergarten and fifth grade, the average trajectory of students who were LM-iLEP converged with that of students who shared demographic risk factors (i.e., were of the same ethnicity and SES). The third key finding is that LM learner status moderated the negative effect of attending a high-poverty school. The differences in reading

Table 7  
*Predicted Effect Sizes in Reading Achievement Between Students Attending Schools With High and Low Concentrations of Poverty by English Language Proficiency Group (N = 17,385)*

Grade	Effect sizes (Cohen's <i>d</i> )		
	Native English speakers	iFEP students	iLEP students (weighted average)
Spring, Kindergarten	−0.16	−0.27	0.10
Spring, 3rd grade	−0.21	−0.12	0.04
Spring, 5th grade	−0.20	−0.04	−0.04

*Note.* Positive differences favor low-poverty schools (in which 25% of students receive free or reduced lunch) in comparison with high-poverty schools (in which 75% of students receive free or reduced lunch). Effect sizes are fitted for Latino students of average socioeconomic status attending public schools of average concentration of students of color. iLEP = initially limited English proficiency; iFEP initially full English proficiency.

trajectories between students who attended high- and low-poverty schools were smaller for both groups of LM learners than for native English speakers. Moreover, the trajectories of LM learners in high-poverty schools tended to converge over time on those of LM learners in low-poverty schools (unlike the growth trajectories of native English speakers who attended schools of differing concentrations of poverty).

### *Reading and Language Development in English: Who's Falling Behind?*

The results of this study suggest that LM learners in the United States who enter kindergarten orally proficient in English reach levels of English reading achievement that are equivalent to or higher than those reached by native English speakers. By fifth grade their English reading achievement was not significantly different from the national average and was approximately .16 standard deviation higher than demographically similar native English speakers in high-poverty schools. On the other hand, LM learners who entered kindergarten with limited English proficiency had large, persistent deficiencies in English reading achievement. Although the estimates of these gaps depended substantially on whether demographic risk factors were taken into account and on the stage at which students gained enough English proficiency to take the reading test, none of the estimates of these gaps were small. Even the students who acquired English most rapidly, in the course of a year of kindergarten, continued to lag behind the national average for native English speakers by more than .33 standard deviation in third and fifth grade.

The strong performance of LM learners in this study who entered kindergarten fluent in English both reinforces the research base on bilingualism and refocuses attention on the issue of English proficiency. These findings suggest that exposure to a language other than English before kindergarten does not, by itself, place students on a differential trajectory for English reading achievement. This concurs with researchers who have often argued that bilingualism is not inherently detrimental to reading development (e.g., August & Hakuta, 1997; Snow, 1992); rather, it suggests that limited English proficiency and the constrained access to the school curriculum it entails are the characteristics that put students at elevated risk for English reading difficulties. It also suggests U.S. schools may not be failing all bilingual students, but that the most underserved population consists of those who enter school with limited English skills.

Additionally, in describing the English reading growth of LM learners who enter kindergarten with limited English, these findings support the differential skills hypothesis and related theoretical models (e.g., RAND Reading Study Group, 2002). For these learners, moderate deficiencies in reading at the end of kindergarten grow into large deficiencies as text demands increase, likely in part because of their persistently low vocabulary levels. Stanovich (1986) has hypothesized that a reciprocal relationship between reading ability and vocabulary knowledge underlies individual differences in reading that increase over time, especially during the late elementary grades as students transition from learning to read, a stage in which they rely largely on basic vocabulary acquired through conversation, to reading to learn, a stage at which readers are expected to acquire sophisticated vocabulary and content

knowledge through reading (Chall, 1983; RAND Reading Study Group, 2002).

For LM learners who enter kindergarten with limited vocabulary knowledge in English, this developmental process can be a downward spiral that accelerates in later years, as students not only lack the vocabulary to comprehend and analyze texts, but then fail to gain the vocabulary and knowledge from texts that are essential to later success with English reading. Even the group of students in the present analysis who nominally acquired oral English proficiency by the end of first grade (as indicated by passing the Pre-K LAS assessment) continued to have slow rates of growth in English reading across the elementary school years. This supports the assertion of second-language researchers that acquiring basic interpersonal English is a simpler task than acquiring the academic language and vocabulary necessary to comprehend academic texts in English (e.g., Collier, 1989; Cummins, 1979; Scarcella, 2004). The difficulty of the latter task is compounded by the limited instructional time that is typically devoted to vocabulary and language development (e.g., Roser & Juel, 1982; Scott, Jamieson-Noel, & Asslin, 2003; Watts, 1995).

A limitation of the present study is that it used only a single global measure of English reading and thus could not support the examination of differential development in componential reading skills. Future large-scale longitudinal research of this kind should consider including standardized measures of multiple constructs related to reading, such as word reading, vocabulary, and comprehension processes. Such research should also consider including assessments of native language skills and collecting data on students' opportunities to develop native language skills, although such assessments should supplement rather than replace assessments in English to provide a complete picture of students' achievement.

### *Incorporating Demographic Factors: Catching Up to Whom?*

The second key finding is that the growth trajectories in reading of LM learners who entered kindergarten with limited English proficiency diverged from the national average for native English speakers but converged with those of native English speakers with whom they shared demographic risk factors. When ethnicity and SES were not taken into account, differences in English reading between native English speakers and students who were LM-ILEP grew between kindergarten and fifth grade (from approximately .60 standard deviation to .80 standard deviation). However, when ethnicity, SES, and school demographics were taken into account, these differences narrowed between kindergarten and fifth grade (from approximately .60 standard deviation to less than .40 standard deviation in schools of average concentration of poverty).

Given that the reading achievement of native English speakers with multiple demographic risk factors who attended high-poverty schools was well below the national average, it is unfortunate that LM learners who entered kindergarten with limited English did not surpass this low standard. Nonetheless, this finding echoes the suggestion of Lesaux et al. (2007) and others that the confounding of SES and LM learner status in many settings may obscure which part of the achievement gap is attributable to LM learner status. It also indicates that the levels of English reading achievement among many LM learners in the upper elementary grades may be fairly similar to those of their

classmates. Future research should investigate the degree to which these two groups' academic needs, instructional profiles, and responsiveness to intervention also overlap.

### *The Moderating Effect of LM Learner Status on School Poverty*

The third key finding is that the effects of school poverty differed as a function of LM learner status, such that differences between growth trajectories in reading associated with school poverty were greater for native English speakers than for LM learners. These findings suggest that the negative effects of concentrated poverty are actually less severe for LM learners than for native English speakers. This somewhat surprising interaction effect can be interpreted in several ways.

One interpretation of this moderating effect is that LM learners have resilience to the effect of school poverty because of resources associated with their LM learner status, such as cognitive advantages provided by bilingualism or unobserved family resources. This interpretation may explain the success of LM learners who enter school proficient in English; although the subgroup of these learners who entered high-poverty schools was lower than their counterparts in low-poverty schools by .25 standard deviation in the spring of kindergarten, they reached equivalent levels by the spring of fifth grade. As displayed in Figure 2, students who were LM-iFEP reached high reading levels by fifth grade whether they attended high- or low-poverty schools. This success represented levels of achievement that were equivalent to those of their native-English speaking classmates in low-poverty schools and higher levels than those of such classmates in high-poverty schools.

Future research is certainly needed to investigate the sources of this resilience. Two explanations are worth considering. First, given that this group of learners entered kindergarten proficient in English and with at least some proficiency in another language, we might suspect that they have cognitive or linguistic advantages because of being raised in a bilingual home. This explanation draws empirical support largely from the work of Bialystok (1988, 2005), who has argued that bilingual children have advantages in specific reading-related skills, particularly in tasks involving meta-cognitive and meta-linguistic awareness. One aspect of meta-linguistic awareness that is particularly important in the process of learning to read for both native English speakers and LM learners is phonological awareness (for reviews, see Adams, 1990; August & Shanahan, 2006; National Institute of Child Health & Human Development, 2000). However, there is mixed evidence as to whether bilingualism facilitates development of phonological awareness. Bialystok, Majumder, and Martin (2003) found advantages for Spanish-English bilinguals on one phonological awareness task but failed to replicate this finding when using different tasks or among speakers of other languages, whereas other studies have found average to below average levels of phonological awareness among LM learners (e.g., Lesaux & Siegel, 2003; Manis et al., 2004).

A second explanation for the high reading levels attained by students who were iFEP may be the presence of family resources associated with recent immigration that are not adequately captured with a single measure of SES. For instance, the National Research Council (1998) concluded that children in families who have recently immigrated have overall better physical and psycho-

logical health and engage in fewer risky behaviors than their counterparts in second- and third-generation immigrant families. Similarly, in their study of children of immigrants, Suarez-Orozco and Suarez-Orozco (2001) found that an emphasis on parents' current occupation and salary obscured the bimodal distribution of other resources among immigrant families, including parental educational levels; whereas some parents immigrated to the United States because of their own limited educational and occupational opportunities in their home countries, others had high levels of education that allowed them to navigate the process of immigration. Such resources and related family behaviors may serve as protective factors against the negative effects of attending high-poverty schools for some LM learners and thus explain differences within the population of LM learners. In examining heterogeneity among Spanish-speaking LM learners, Reese et al. (2000) found that family literacy practices and grandparents' education predicted seventh-grade reading outcomes. Although this evidence suggests that many immigrant families may have resources that explain the resilience of some LM learners to school poverty, more research is needed to examine the links between these resources and English reading development.

Similarly, the negative effects of school poverty may be less severe for LM learners who enter kindergarten with limited English proficiency. However, the consistently low performance of these learners in both high- and low-poverty schools might best be characterized as a low baseline of depressed development. Unlike those students who were LM-iFEP and entered low-poverty schools with average English reading achievement, students who were LM-iLEP entered school with low levels of English reading, regardless of whether they entered high- or low-poverty schools. Over time, they maintained equivalently low levels despite differences in their schooling contexts, which is more suggestive of the difficulties of these learners in low-poverty schools across the elementary school years than the resilience of their counterparts in high-poverty schools.

It is possible that this subset of LM learners does not benefit from the same linguistic and family resources as do LM learners who are bilingual at school entry. However, it may also be that low-poverty schools underserve these learners compared with LM learners with higher initial English language and literacy levels. Specific instructional programs to develop English proficiency may be scarce in schools that lack funding from Title I or Title III. Teachers in such schools may be less prepared to serve the needs of students with limited English proficiency or may have low expectations for these learners. Alternatively, given the critical role of language in reading development, it is possible that students who enter schools with limited English proficiency cannot attain a threshold of English proficiency at which they could benefit from the resources that a low-poverty school has to offer (at least in the absence of early and extensive intervention). Future research should investigate the instructional and contextual factors at play in LM learners' English reading development in low-poverty schools, especially given the limited research on these learners outside of urban centers and the growing numbers of LM learners in schools of all demographic constitutions (Capps et al., 2005).

In summary, this study suggests that students who enter school with limited proficiency in English are at great risk for reading difficulties and have pressing instructional needs that are currently not addressed in elementary schools in the United States. Further-

more, the findings illustrate the great risk also experienced by other students of color who come from low-SES backgrounds and suggest that the academic needs of these two groups of learners may be quite similar, particularly in high-poverty schools.

### New Editors Appointed, 2010–2015

The Publications and Communications Board of the American Psychological Association announces the appointment of 4 new editors for 6-year terms beginning in 2010. As of January 1, 2009, manuscripts should be directed as follows:

- *Psychological Assessment* (<http://www.apa.org/journals/pas>), **Cecil R. Reynolds, PhD**, Department of Educational Psychology, Texas A&M University, 704 Harrington Education Center, College Station, TX 77843.
- *Journal of Family Psychology* (<http://www.apa.org/journals/fam>), **Nadine Kaslow, PhD**, Department of Psychiatry and Behavioral Sciences, Grady Health System, 80 Jesse Hill Jr. Drive, SE, Atlanta, GA 30303.
- *Journal of Experimental Psychology: Animal Behavior Processes* (<http://www.apa.org/journals/xan>), **Anthony Dickinson, PhD**, Department of Experimental Psychology, University of Cambridge, Downing Street, Cambridge CB2 3EB, United Kingdom
- *Journal of Personality and Social Psychology: Personality Processes and Individual Differences* (<http://www.apa.org/journals/psp>), **Laura A. King, PhD**, Department of Psychological Sciences, University of Missouri, McAlester Hall, Columbia, MO 65211.

**Electronic manuscript submission:** As of January 1, 2009, manuscripts should be submitted electronically via the journal's Manuscript Submission Portal (see the website listed above with each journal title).

Manuscript submission patterns make the precise date of completion of the 2009 volumes uncertain. Current editors, Milton E. Strauss, PhD, Anne E. Kazak, PhD, Nicholas Mackintosh, PhD, and Charles S. Carver, PhD, will receive and consider manuscripts through December 31, 2008. Should 2009 volumes be completed before that date, manuscripts will be redirected to the new editors for consideration in 2010 volumes.

# From Reading to Spelling and Spelling to Reading: Transfer Goes Both Ways

Nicole J. Conrad  
Saint Mary's University

This study compares the effects of practice spelling and reading specific words on the orthographic representations in memory involved in reading both practiced words and new, unfamiliar words. Typically developing readers in Grade 2 (mean age = 7 years, 7 months) participated in a training study examining whether transfer can occur between reading and spelling following a series of reading and spelling practice sessions. Practice consisted of either repeated reading or repeated spelling of words with shared orthographic rime patterns. A series of mixed analyses of variance was used to examine generalization within skill and transfer across skill. Following practice, word-specific transfer across skill was found. Specifically, children were better able to spell words they had practiced reading and to read words they had practiced spelling. In addition, generalization to new words with practiced rime units was found both within a skill and across skills. However, transfer from spelling to reading was greater than transfer from reading to spelling. Results indicate that the orthographic representations established through practice can be used for both reading and spelling. Subsequently, reading and spelling curricula should be coordinated to benefit children maximally.

*Keywords:* reading, spelling, orthographic knowledge, intervention

Fluent reading rests on word recognition, among other skills. If difficulty is encountered recognizing individual words, few, if any, higher order skills such as comprehension can operate (Laberge & Samuels, 1974; Snowling, 2000). Many models of reading propose that fluent reading of words results from the rapid recognition of letter sequences as a single unit within a word (Adams, 1990; Ehri, 1997). This rapid recognition depends on previously established memory representations of letter patterns that occur frequently within a language (i.e., orthographic representations). Memory representations of these letter sequences that are accurate and detailed contain information about the graphemes (i.e., letters), phonemes (i.e., sounds), and their mappings (Ehri, 1997) and are thought to be established through practice with words. In the present study, I compare two types of practice through which children may establish the orthographic representations necessary for fluent reading. Specifically, I examine whether the orthographic representations established through practicing spelling words may facilitate reading words.

Models of reading suggest that the orthographic memory representations necessary for fluent reading are established primarily through the repeated phonological recoding of words (Ehri, 1997,

2005; Share, 1995). Repeated practice mapping phonemes onto graphemes allows children to set up the representations necessary to support fluent word reading (Cunningham, Perry, Stanovich, & Share, 2002; Share, 2004). With continued practice, these memory representations become increasingly accurate, reflecting the constituent letter sequences of words and their phonological code (Perfetti & Hart, 2001). The idea that practice is necessary for the improvement of reading skills is not new. For instance, Nathan and Stanovich (1991) declared more than a decade ago that children develop knowledge of orthographic patterns through practice with words, a conclusion supported by the finding that children who read a lot become better readers, whereas children who read little fall further and further behind their peers (Stanovich, 1986).

It has been assumed in the research literature that the best practice takes the form of repeated reading (for a review, see Meyer & Felton, 1999). Practice at reading words enables children to recognize common letter patterns, to map sounds onto letters and letter patterns, and to develop fully specified orthographic representations. In fact, according to the self-teaching hypothesis (Share, 1995, 2004), translating a printed word into its spoken equivalent is the only means through which fully specified orthographic representations can be established. Several studies have supported the important role of repeated reading for improving word recognition skills in terms of both accuracy and speed (e.g., Berends & Reitsma, 2006; Levy, 2001; Thaler, Ebner, Wimmer, & Landerl, 2004). These studies focused on providing practice with a set of specific orthographic patterns (e.g., *-uck*) through repeated reading of words containing these patterns. Their goal was to use such practice to set up orthographic representations that might facilitate reading new, nonpracticed words that contained the same orthographic patterns. For example, Levy (2001) reported a study in which children with poor reading skills in Grade 2 were pre-

---

sented with words that shared a rime unit (e.g., *-uck*) blocked together for repeated reading practice. Results indicated a benefit in reading accuracy for the actual words children had practiced reading, but little generalization to new words that contained the practiced orthographic patterns. Similar results using the same methodology have been found with Dutch children (Berends & Reitsma, 2006) and German children (Thaler et al., 2004) with poor reading skills. Together, the results of these training studies suggest that repeated reading is effective in setting up word-specific orthographic representations that facilitate reading those specific words. However, another measure of the success of a training program lies not only in its word-specific effects but also in how well children can generalize what they have learned through training to reading new words. As the studies reviewed here found little generalization to new material, there is a need to explore other methods of practice that might establish orthographic representations that can aid in reading new or unfamiliar words.

The current study explored whether spelling practice would contribute to the establishment of orthographic representations that facilitate reading. Both Ehri (1997, 2005) and Perfetti (1997) proposed that reading and spelling share mental representations, or knowledge sources, suggesting that what is learned through one skill should benefit the other skill (e.g., Ehri, 1997; Perfetti, 1997), albeit not to the same degree. Spelling is the more difficult task and requires a better quality representation (Perfetti, 1992). Thus, although reading can be supported by incomplete representations, spelling cannot. For example, individuals can read the word *occasion* even if their representation contains the letter pattern *oc?a-s?ion*, whereas this representation might lead to an incorrect spelling (Perfetti, 1997; Perfetti & Hart, 2001). Like reading, spelling provides practice mapping phonemes onto graphemes, but because it requires the production rather than the recognition of letter patterns, full attention to all letters in a word is necessary. In addition, the motor act involved in spelling may provide an additional cue that is incorporated into the memory representation (Hulme, 1981). This increased thoroughness of processing letters may produce representations that are more complete than those established through reading alone. Thus, a high-quality representation established through practice spelling a word should support reading that same word; however, the quality of the representation established from practice reading a word would not necessarily ensure that word could be spelled.

Few studies have examined word-specific transfer from reading to spelling and spelling to reading concurrently, preventing a direct comparison of the effectiveness of different types of practice. However, a number of studies have examined the benefit to spelling of practicing reading. For example, Share (2004) found that practice reading Hebrew words in a text facilitated spelling those same words for children in Grade 3 but not for children in Grade 1. In the English language, Ehri has conducted a number of studies in which practice reading nonwords (Ehri, 1980) and words (Ehri & Wilce, 1986) has enhanced the spelling of those nonwords and words for children in Grade 2. On the basis of these findings, Ehri (1997) concluded that reading practice sets up word-specific representations that can support spelling those words. However, the amount of transfer from reading to spelling was not 100%. Following practice reading nonwords, Ehri (1980) found that 69% of those nonwords were spelled correctly; following practice reading real words (Ehri & Wilce, 1986), only 31% of practiced words

were spelled correctly. Other studies have failed to find any effects on spelling following repeated reading practice. A series of studies reported by Bosman and van Orden (1997) have suggested that reading practice is not the most effective way to learn to spell. In these studies, more repetitions of reading words did not result in a corresponding improvement in spelling those words for a group of beginning Dutch readers. Because of these conflicting results, it is unclear how reading practice benefits spelling.

Our understanding of how practice spelling benefits reading is also incomplete. Teaching general alphabetic knowledge through spelling, such as mapping phonemes onto graphemes, has had some influence on reading skills (e.g., Berninger et al., 1998; Ehri & Wilce, 1987). However, when word-specific spelling practice is used (repeated spelling of a set of words), there appears to be little benefit to reading those words. For example, Roberts and Ehri (1983) tested children in Grade 2 who practiced spelling a list of pseudowords through two different techniques. Although the groups differed in spelling accuracy for those pseudowords following spelling practice, the groups did not differ in the number of pseudowords read correctly or in the speed of reading those pseudowords following spelling practice. Although the results might suggest that what is learned through spelling does not transfer to reading, such a conclusion is inconsistent with theories of reading and spelling (e.g., Ehri, 1997; Perfetti, 1997). In fact, Ehri (1997) suggested that further study is needed to understand fully whether word-specific information gained through spelling practice can benefit reading.

Orthographic representations established through practice with words can also support the reading of unfamiliar words, either through analogy from known words containing shared letter sequences (e.g., Ehri & Robbins, 1992; Goswami, 1986) or through the induction of sublexical relations (e.g., Fletcher-Flinn & Thompson, 2004; Thompson, Cottrell, & Fletcher-Flinn, 1996) that provide readers with general knowledge of the relations between orthographic and phonological components that are common to words the child has experienced. Whereas the above-mentioned studies examining generalization following repeated reading of words with poor readers have failed to find meaningful generalization to reading new words (e.g., Berends & Reitsma, 2006; Levy, 2001; Thaler et al., 2004), studies using different methodologies have indicated that generalization to reading unfamiliar words (e.g., Goswami, 1986) after practice reading and to spelling unfamiliar words (e.g., Bosse, Valdois, & Tainturier, 2003; Campbell, 1985) following practice spelling can occur. However, whether generalization to new words can occur across skills (i.e., from spelling to reading or reading to spelling) has not been directly examined in the literature.

### The Present Study

Presently, our understanding of the transfer between reading and spelling is incomplete. Theoretically, practice spelling should benefit reading more than practice reading should benefit spelling, yet studies to date have not allowed a direct comparison of the reciprocal benefits. The current study explores these issues in a group of typically developing readers to examine the nature of transfer between skills and the degree to which it can occur. Children received either repeated practice spelling or repeated practice reading a list of words containing families of words with shared

orthographic rime units. To examine both generalization within and across skill following practice, children were asked to read and spell a new list of words, some of which contained the practiced orthographic pattern. To compare word-specific transfer across skill, children also spelled the words they had practiced reading or read the words they had practiced spelling. Children were also matched on a number of skills related to reading and spelling, including vocabulary (e.g., Beck & McKeown, 1991), orthographic knowledge (e.g., Barker, Torgesen, & Wagner, 1992), and phonological skill (e.g., Bradley & Bryant, 1983), to reduce the likelihood that any benefits after practice were the result of pre-existing differences in these skills. This design enabled several questions related to the benefits of each type of practice to be addressed.

Because spelling a word requires a more complete representation than does reading a word, spelling practice should establish a more detailed and accurate orthographic representation than reading practice, which results in the following four predictions: First, generalization within skill was expected after both reading and spelling practice because typically developing readers in Grade 2 have the decoding skills necessary for making analogies and inducing the sublexical relations between graphemes and phonemes (Ehri & Robbins, 1992). Second, generalization to spelling unfamiliar words after spelling practice should be greater than to reading unfamiliar words after reading practice because of the more accurate and detailed orthographic representation established through spelling practice. Third, word-specific transfer from spelling to reading should be greater than from reading to spelling because accurately spelling a word should ensure that word can be read, whereas accurately reading a word does not necessarily ensure that word can be spelled. Fourth, transfer to unfamiliar words from spelling to reading should be greater than from reading to spelling because of the more accurate and detailed orthographic representation that readers have for reading and spelling new words.

An investigation into these issues can not only provide us with information regarding the nature of the representations that underlie reading and spelling, but perhaps more important, results can inform curricular design as to how to coordinate reading and spelling instruction to benefit students maximally.

## Method

### Participants

Forty-one children (22 boys and 19 girls) in Grade 2, with a mean age of 7 years, 7 months, participated. They were selected from 60 children screened in five schools in a rural area in western Canada. The average yearly income in these rural areas, according to 2000 census data, was \$23,449, below the national average of \$43,298 (Statistics Canada, 2002). All children spoke English as a first language. Each child was administered the Word Identification subtest of the Woodcock-Johnson Tests of Achievement—Third Edition (WJ-III; Woodcock, McGrew, & Mathers, 2001). Forty-four children scoring below a standard score of 115 and above a standard score of 85 (1 standard deviation from the mean) on the WJ-III were identified as average readers and included in the study. Of these 44 children, 1 was identified as having attention deficit/hyperactivity disorder and excluded from data analyses, and

2 were excluded because of noncompliance or incomplete data. Thus, the final sample consisted of 41 children, 20 children in the reading practice group (readers) and 21 children in the spelling practice group (spellers).

### Pretest Measures

**Reading skill.** Reading skill was measured using the Word Identification subtest of the WJ-III. This is a standardized test in which children read a list of words that become progressively more difficult (e.g., *see*, *bought*, and *investigate*). Testing is discontinued after six errors in a row. Reported corrected split-half reliability for 7-year-olds on this subtest is .97. Dependent measures used in data analyses were standard scores (age normed), with a mean of 100 and standard deviation of 15.

**Spelling skill.** Spelling skill was measured using the Spelling subtest of the WJ-III. This is a standardized test measuring written spelling. Words are orally presented to the child and become progressively more difficult (e.g., *hat* and *league*). Testing is discontinued after six errors in a row. Reported corrected split-half reliability for 7-year-olds on this subtest is .91. Dependent measures used in data analyses were standard scores (age normed) with a mean of 100 and a standard deviation of 15.

**Vocabulary.** Receptive vocabulary was assessed using the Picture Vocabulary subtest of the WJ-III. Children are asked to identify pictures of objects (e.g., fish, umbrella, and moccasins), and testing is discontinued after six errors in a row. Reported corrected split-half reliability for 7-year-olds on this subtest is .71. Dependent measures used in data analyses were standard scores (age normed) with a mean of 100 and a standard deviation of 15.

**Phonological awareness.** The Test of Auditory Analysis Skills (Rosner, 1979) was administered to measure phonological awareness. This test is a 13-item sound-deletion task in which children are to repeat a word spoken by the experimenter after deleting an indicated sound at the beginning, middle, or end of the word (e.g., say *game* without the /g/). The measure used for analyses was proportion correct. Cronbach's alpha internal consistency reliability for this sample was .72.

**Orthographic knowledge.** A two-alternative forced-choice task was designed using a subset of 20 items from the orthographic choice task of Olson, Forsberg, Wise, and Rack (1994). This new test includes 20 pairs of words, with each pair consisting of the correct spelling of a target word and a homophonic nonword spelling (e.g., *rain-rane* and *tertle-turtle*). Children indicated which of the two alternatives was the correct spelling for a target word used in a sentence. Because the word pairs are phonologically similar but orthographically dissimilar, children had to use word-specific knowledge of spelling and could not rely on phonological information to complete this task. The dependent measure was proportion correct. Cronbach's alpha internal consistency reliability for this sample was .62.

### Design

**Practice phase.** Children were randomly assigned to one of two groups, one of which received repeated practice reading a list of 40 words and one of which received repeated practice spelling the same list of 40 words.

The 40 practice words were chosen from eight different orthographic families. There were eight groups of five words that all

shared an orthographic rime (e.g., *chore*, *shore*, *snore*, *core*, and *sore*). All words within a family had consistent phonological-orthographic correspondences; that is, all orthographic patterns within a family of words sounded the same. Practice words are presented in Appendix A.

In the reading group, words were presented one at a time on 4-in.  $\times$  6-in. flashcards, with words that shared an orthographic rime presented one after another. Previous studies have indicated that learning is facilitated with a blocked presentation (e.g., Levy, 2001). The shared orthographic pattern within a family of words was printed in red to make the orthographic pattern maximally salient. Order of families within a trial and order of words within a family were randomly ordered across participants and, within participants, across trials. Participants were asked to read each word as accurately as possible. If a participant did not respond within 5 s, or responded incorrectly, the experimenter provided whole-word feedback by reading the word aloud. The dependent measure was the proportion of words read correctly. One practice trial was defined as reading through the list of 40 words once. Participants completed four trials a day over 4 days for a total of 16 repetitions.

The same list of 40 words was used for spelling practice. Words were presented orally by the experimenter. Words that shared an orthographic rime pattern were presented one after another. Participants printed the spelling of each word on a sheet of lined notepaper using a No. 2 pencil. On completion of each word, participants were visually presented with the word using the same flashcards as used in the reading practice condition. Participants self-corrected their spellings following each word. The dependent measure was the proportion of words spelled correctly before self-correction. All other aspects of spelling practice were the same as in the reading practice condition.

It is important to note that because children were able to view their written responses and the feedback provided for self-correction, it is possible that children in this condition were also reading the words, although they were not explicitly instructed to do so. This potential confound is inevitable when using written spelling; thus, this practice condition might more aptly be called a "spelling + reading" condition.

**Postpractice phase.** During the postpractice test phase, generalization within a skill and both word-specific and general transfer across skill were measured. Word-specific transfer across skill was assessed by having the participants either read or spell the 40 practice words, doing the opposite of what they had done during practice. To examine generalization within skill and generalization across skill, two different lists (List A and List B in Appendix B) of 64 new words were constructed. Each of these lists was made up of 32 new words that contained a practiced orthographic rime pattern (i.e., transfer words) and 32 new words that did not contain a practiced orthographic rime pattern (i.e., control words). All eight orthographic families were tested, with four new words from each family in the list. Orthographic patterns were not repeated across the two lists for the new words with unpracticed patterns to ensure that children did not become familiar with the patterns through testing. The lists were equal in the number of new words with a two-consonant cluster beginning and a one-consonant beginning. Word lengths were balanced across the two lists.

New words with or without practiced orthographic rime units and words within an orthographic family were randomly distrib-

uted throughout the list of 64 words. Participants read one list of 64 new words and spelled the other list of 64 new words. Lists were counterbalanced across participants such that half of the spellers and half of the readers spelled List A and read List B, and the other half of spellers and readers read List A and spelled List B. In addition, half of the spellers and half of the readers did the spelling first, and half of the spellers and half of the readers did the reading first. Presentation of test material was the same as presentation of material during the practice phase, except that no feedback was provided during the test phase. The proportion of words read or spelled correctly was the dependent measure. Table 1 presents an illustration of the design of the study for one child in the spelling group. Please note that only one orthographic family is illustrated in this example.

### Procedure

The selection and pretest measures (WJ-III reading, spelling, vocabulary, orthographic choice, and Test of Auditory Analysis Skills) were individually administered in one 30-min session. All other sessions involved individual testing as well. Over the next 4 days, participants either read or spelled the list of 40 practice words four times each day, in sessions lasting between 10 and 30 min. Spelling sessions generally lasted longer than did reading sessions. On the 5th day, posttest measures were administered in one 30-min session. All children began with the word-specific transfer task, followed by either the within-skill or across-skill generalization task. Order of presentation of these two tasks was counterbalanced across participants.

## Results

### Group Comparisons

Analyses of means on the pretest measures, presented in Table 2, were conducted to ensure that there were no preexisting differences between the two practice groups on any of the reading-related skills. A series of independent-sample *t* tests with practice group as the independent factor indicated that there were no reliable differences between groups on word identification,  $t(39) = -0.42$ ; spelling,  $t(39) = -1.76$ ; vocabulary,  $t(39) = 0.41$ ; orthographic knowledge,  $t(39) = -0.023$ ; or phonological processing

Table 2  
Means and Standard Deviations on Pretest Measures

Practice group	Word Identification	Spelling	Vocabulary	TAAS	Orthographic choice
Readers ( <i>n</i> = 20)					
<i>M</i>	100.25	100.90	107.25	.62	.74
<i>SD</i>	7.86	6.30	7.65	.24	.28
Spellers ( <i>n</i> = 21)					
<i>M</i>	101.33	104.71	106.29	.69	.75
<i>SD</i>	8.69	7.51	7.59	.21	.33

Note. Word Identification, Spelling, and Vocabulary are standard scores ( $M = 100$ ,  $SD = 15$ ) from the Woodcock-Johnson Tests of Achievement—Third Edition; Test of Auditory Analysis Skills (TAAS) and Orthographic Choice are proportion correct.

skill (Test of Auditory Analysis Skills),  $t(39) = -0.92$ , all  $ps > .05$ . Therefore, any benefits in reading or spelling outcome measures following the practice phase cannot be attributed to any confounds of preexisting differences in these reading-related skills.

### Practice Results

Level of performance across practice trials is presented in Figure 1. It is important to remember that the 40 words practiced were the same for both groups. What differed was the type of practice. For the readers, the mean proportion of words read correctly across trials is presented. For the spellers, the mean proportion of words spelled correctly across trials is presented. As illustrated in Figure 1, performance of both groups improved over trials. This observation was supported by a  $2 \times 16$  mixed analysis of variance with group (speller or reader) as the between-subject factor and

trial (1–16) as the within-subject factor. A significant main effect of trial was found,  $F(15, 585) = 41.70$ ,  $p < .001$ ,  $\eta^2 = .52$ . No other effects were significant, illustrating that both groups improved equally over trials. Although the readers were consistently slightly more accurate than the spellers, groups did not reliably differ in overall accuracy.

### Generalization Within Skill

Table 3 presents the proportion of new words with and without practiced rime patterns read correctly by the readers and spelled correctly by the spellers. A  $2 \times 2$  mixed analysis of variance, with practice group (reader or speller) as the between-subject factor and word type (practiced or unpracticed) as the within-subject factor, revealed a significant main effect of word type,  $F(1, 39) = 60.00$ ,  $p < .001$ ,  $\eta^2 = .61$ , and a significant interaction between word type and group,  $F(1, 39) = 5.53$ ,  $p < .05$ ,  $\eta^2 = .12$ . Simple effects analyses indicated that both groups showed generalization within skill, as readers read more new words with practiced rime patterns than new words with unpracticed rime patterns, and spellers spelled more new words with practiced rime patterns than new words with unpracticed rime patterns. However, generalization was not the same for both groups. Although both groups were equally accurate with the new words with practiced units, the difference between new words with and without practiced units was greater for the spellers (25%) than for the readers (13%),  $t(39) = -2.35$ ,  $p < .05$ ,  $d = 0.75$ , reflecting the spellers' less accurate performance with new words with unpracticed units.

### Transfer Across Skill

Transfer across skill was tested in two ways. First, I examined word-specific transfer to determine whether practice reading (or spelling) a specific word facilitates spelling (or reading) that

Figure 1. Proportion of words read and spelled correctly during the practice phase.

Table 3  
*Generalization Within Skill: Proportion of New Words With and Without Practiced Patterns Read Correctly by the Readers and Spelled Correctly by the Spellers*

Practice group	New words with practiced units	New words with unpracticed units
Readers ( $n = 20$ )		
<i>M</i>	.79	.65
<i>SD</i>	.20	.24
Spellers ( $n = 21$ )		
<i>M</i>	.74	.49
<i>SD</i>	.19	.23

specific word on a later encounter. Second, I examined generalization across skill—that is, whether practice in reading a set of words with a shared orthographic rime pattern benefits spelling unpracticed words that contain that same rime pattern, and vice versa.

*Word-specific transfer.* Figure 2 presents the proportion of the 40 practice words read and spelled correctly by each group. For the readers, the figure represents the proportion of practice words read correctly on the last trial of practice (Trial 16) and the proportion of practice words spelled correctly on the word-specific transfer task administered after practice. For the spellers, the figure represents the proportion of practice words spelled correctly on the last trial of practice (Trial 16) and the proportion of practice words

read correctly on the word-specific transfer task administered following practice. A  $2 \times 2$  mixed analysis of variance with group (readers or spellers) as the between-subjects factor and task (spelling or reading) as the within-subject factor revealed significant main effects of group,  $F(1, 39) = 27.88, p < .001, \eta^2 = .42$ , and task,  $F(1, 39) = 57.67, p < .001, \eta^2 = .60$ , and a significant interaction between group and task,  $F(1, 39) = 56.15, p < .001, \eta^2 = .59$ . Figure 2 clearly portrays the nature of this interaction. Following spelling practice, the spellers were equally able to read or spell the practice words, illustrating complete transfer from spelling to reading. However, the same is not true for reading practice, where there was less complete transfer to spelling. Practice reading a word did not necessarily ensure that a word could be spelled correctly.

*Generalization across skill.* Table 4 presents results relevant to generalization across skill by illustrating the proportion of practiced and unpracticed words spelled correctly by the readers and the proportion of practiced and unpracticed words read correctly by the spellers on each of the postpractice transfer tasks. I conducted a  $2 \times 3$  mixed ANOVA with practice group (readers or spellers) as the between-subjects factor and word type (practiced, new with practiced pattern, or new without practiced pattern) as the within-subject factor to examine transfer across skill. A significant main effect of word type,  $F(2, 78) = 36.06, p < .001, \eta^2 = .48$ , indicated that both groups were showing transfer across skill. Bonferroni post hoc analyses indicated that both groups were most accurate with the actual words they had practiced, followed

Figure 2. Word-specific transfer across skill: Proportion of practice words read and spelled correctly by both readers and spellers.

Table 4  
*Generalization Across Skill: Proportion of Practiced Words and New Words With and Without Practiced Patterns Spelled Correctly by the Readers and Read Correctly by the Spellers*

Practice group	Practiced words	New words with practiced units	New words with unpracticed units
Readers ( $n = 20$ )			
<i>M</i>	.64	.54	.40
<i>SD</i>	.23	.25	.22
Spellers ( $n = 21$ )			
<i>M</i>	.96	.87	.80
<i>SD</i>	.04	.10	.15

by new words with practiced patterns, which was more accurate than new words with unpracticed patterns. Thus, for both groups, word-specific transfer was greatest, but generalization across skill also occurred.

A significant main effect of group,  $F(1, 39) = 50.23, p < .001$ ,  $\eta^2 = .56$ , indicated that the spellers accurately read more words overall than the readers accurately spelled. The type of practice did not significantly interact with word type.

### Discussion

The main goal of the present study was to examine whether transfer can occur between reading and spelling in typically developing readers. Although research has suggested that the orthographic representations necessary to support fluent reading are established through practice and/or exposure to the printed word, how different types of practice contribute to the development of orthographic knowledge has not been fully investigated. The current results provide strong support for transfer between reading and spelling and suggest that spelling practice may be particularly valuable in setting up orthographic representations that can be used for reading.

Both word-specific and general transfer were found between reading and spelling. That word-specific transfer was greatest suggests that both reading and spelling practice set up word-specific representations that can be used across reading and spelling. However, generalization to new instances across skill also occurs, suggesting that children are able to abstract out the common orthographic pattern to aid in reading or spelling new words. Thus, in addition to building word-specific orthographic representations, children may also be increasing their general orthographic knowledge through reading and spelling. A few explanations are available to account for the generalization across skill found here. Several studies have indicated that children are able to read (e.g., Ehri & Robbins, 1992; Goswami, 1986) and spell (e.g., Bosse et al., 2003; Campbell, 1985) unfamiliar words through analogy to words already known. This account suggests that through reading and spelling practice, readers establish word-specific orthographic knowledge that can then be compared with unfamiliar words.

However, it is also possible that children establish more general knowledge of orthographic consistencies and patterns. For example, Fletcher-Flinn, Thompson, and colleagues (e.g., Fletcher-Flinn & Thompson, 2004; Thompson et al., 1996) have suggested that through practice with words children implicitly acquire knowledge of the relations between orthography and phonology

that are common to words the child has experienced. These "induced sublexical relations" can be at the grapheme-phoneme level or at the level of sequences of graphemes-phonemes. Whereas both explanations account for how a child may read an unfamiliar word, the explanations differ in terms of the nature of the orthographic representation or knowledge that is required. For analogy, the reader must have stored in memory a representation of a word neighbor to the unfamiliar word (e.g., *clock* must be stored to read *block*). In the sublexical relation account, the representation consists of relations formed between grapheme(s) and phoneme(s) that are acquired from all words in the child's reading vocabulary. In the present study, generalization may have occurred across skill as a result of children using analogies from the words they had practiced or through knowledge gained during practice through the induction of sublexical relations. The mechanism through which generalization from reading to spelling and from spelling to reading occurs needs to be further investigated.

Although transfer was found both from reading to spelling and from spelling to reading, the amount of transfer was unequal. At the end of the practice phase, spellers were equally able to read or spell the practice words, illustrating complete transfer from spelling to reading. However, the same was not found after reading practice. Practice reading a word did not necessarily ensure that word could be spelled correctly. This result suggests that the quality of the representations established through reading and spelling practice may differ. Spelling appears to set up a more detailed and accurate representation, as transfer from spelling to reading was significantly greater than transfer from reading to spelling.

The level of generalization within skill found in the present study also suggests that spelling practice may set up more detailed and accurate orthographic representation than practice reading. Although generalization within skill was found after both reading and spelling practice, the gains were significantly greater after spelling practice. That is, after spelling practice, children showed an increase in spelling accuracy between new words with trained and untrained patterns that was greater than the increase in reading accuracy after reading practice. It is important to point out, however, that there was more opportunity for improvement for the spellers, as accuracy for new words with untrained patterns was much lower than for the readers. Together, these results are consistent with theories that suggest that spelling requires a more specified orthographic representation than reading (Perfetti, 1997) and highlight the importance of spelling instruction in the early school years. Such instruction and practice can benefit developing reading skills and spelling skills.

The generalization within skill found in this study was greater than the amount of generalization reported in previous studies using similar methodologies of reading practice (Berends & Reitsma, 2006; Levy, 2001; Thaler et al., 2004). This difference most likely lies in the samples of children used in the various studies. Previous studies examined generalization within poor readers, whereas the present study used average readers. There is evidence to suggest that generalization after practice such as this will differ across skill level. For example, in the reading-by-analogy literature, Ehri and Robbins (1992) demonstrated that readers first had to have a minimal level of decoding skill before they were able to use analogy to generalize from familiar words to unfamiliar words. The goal of the present study was to examine whether transfer and

generalization could occur across reading and spelling in typically developing children. Because the present study indicates that transfer can occur, even with words that are familiar to children, future studies should examine whether practice spelling is a viable method to improve the reading skills of children with reading disabilities.

Last, it is important to note that the present study was a training study to examine whether transfer *can* occur. Despite this fact, there are similarities between the conditions of the current study and what may occur in a naturalistic setting. At the beginning of the practice sessions, children were quite accurate in reading and spelling the practice words, indicating that they already had familiarity with the words. As noted previously, practice with words results in increasingly accurate orthographic representations. In everyday reading and spelling, children are practicing words that are familiar to them, continually improving the quality of the orthographic representations. In addition, spelling a word typically takes longer than reading a word and involves a motor response. The extra time spent on spelling or the additional motor cues may help account for the greater benefits of spelling practice. Also, the spelling practice condition may more appropriately have been labeled as a "spelling + reading" condition, as it involved both reading and spelling. When children were provided with visual feedback to correct their spelling, they may also have been reading words. However, this also occurs when children are spelling in their everyday lives. They spell the word. Afterward, it is visible for them to read. Although familiarity, time spent practicing, the motor response, and the confound of spelling involving reading are important considerations for future research to help identify which specific components of spelling practice are most influential in setting up detailed orthographic representations, from an educational perspective the results still provide strong support for the benefit of spelling practice in addition to reading practice.

In conclusion, the present study illustrates that transfer between reading and spelling occurs in both directions. Although repeated reading and spelling of isolated words is perhaps not the most practical route through which children establish orthographic representations, the findings from the current study do inform how we should teach our children to read and spell. Reading and spelling programs should be coordinated to benefit students maximally. In addition, transfer from spelling to reading was greater than transfer from reading to spelling, suggesting that spelling practice may establish a more detailed and accurate orthographic representation than does practice reading. This finding indicates that instruction in spelling may be particularly valuable in the early school years to aid in developing reading skills. Finally, results suggest that spelling practice should be further investigated to determine whether such practice is a viable method to improve the reading skills of children with reading disabilities.

# A Meta-Analysis of Single Subject Design Writing Intervention Research

Leslie Ann Rogers and Steve Graham  
Vanderbilt University

There is considerable concern that students do not develop the writing skills needed for school, occupational, or personal success. A frequent explanation for this is that schools do not do a good job of teaching this complex skill. A recent meta-analysis of true- and quasi-experimental writing intervention research (S. Graham & D. Perin, 2007a) addressed this issue by identifying effective instructional writing practices. The current review extends this earlier work by conducting a meta-analysis of single subject design writing intervention studies. The authors located 88 single subject design studies where it was possible to calculate an effect size. They calculated an average effect size for treatments that were tested in 4 or more studies, using a similar outcome measure in each study. This resulted in the identification of 9 writing treatments that were supported as effective. These were strategy instruction for planning/drafting, teaching grammar and usage, goal setting for productivity, strategy instruction for editing, writing with a word processor, reinforcing specific writing outcomes, use of prewriting activities, teaching sentence construction skills, and strategy instruction for paragraph writing.

**Keywords:** writing, composition, meta-analysis, instruction, single subject design

According to the most recent National Assessment of Educational Progress (Persky, Daane, & Jin, 2003), many children do not learn to write well enough to meet classroom writing demands. The writing of 2 out of every 3 students in Grades 4, 8, and 12 was below grade-level proficiency. Concerns about writing are not limited to elementary and secondary schools, however, as college instructors estimated that 50% of high school graduates are not prepared for college-level writing demands (Achieve, Inc., 2005). Moreover, American businesses spend \$3.1 billion annually for writing remediation (National Commission on Writing, 2004). In 2003, these problems led the National Commission on Writing to conclude that the writing of students in the United States “is not what it should be” (p. 7).

Students who do not learn to write well are at a disadvantage. At school, weaker writers are less likely than their more skilled peers to use writing to support and extend learning in content classrooms (Graham & Perin, 2007a). Their grades are more likely to suffer, particularly in classes where writing is the main tool (e.g., via tests and papers) for assessing progress (Graham, 2006b). Their chances of attending college are reduced, as writing is now used to evaluate many applicants’ qualifications. At work, writing has become a gateway for employment and promotion (see reports by the National Commission on Writing, 2004, 2005). Employees in business and government, for instance, are expected to produce written documentation, visual presentations, memoranda, technical re-

ports, and electronic messages. Socially, adults who do not write well may not be able to participate fully in civic life, as e-mail and text messaging have progressively supplanted telephones as a primary means for communicating. On a personal level, people use writing to explore who they are, to combat loneliness, and to chronicle their experiences. Writing about one’s feelings and experiences, for example, is beneficial psychologically and physiologically (see Smyth, 1998, for a meta-analysis of this research).

Why do so many students not write well enough to meet grade level demands? One possible reason is that schools do not do an adequate job of teaching this complex skill. The National Commission on Writing (2003) charged that this is the most neglected of the three *Rs* in the American classroom and offered the following recommendations: double time students spend writing, assess their writing progress, use technology to advance the learning and teaching of writing, and better prepare teachers to teach writing. The impact of these recommendations is likely to be reduced if teachers do not use effective instructional practices.

## Need for a Meta-Analysis of Writing Interventions Tested Via Single Subject Design Studies

A useful approach for identifying effective writing practices is to conduct systematic reviews of writing intervention research. Since the mid-1980s there have been a number of meta-analyses of the writing intervention literature (e.g., Hillocks, 1986; Graham & Perin, 2007a, 2007b). With meta-analysis, an effect size is computed for each empirical study investigating a specific treatment and then is averaged across studies to provide a summary statistic on the intervention’s effectiveness (Lipsey & Wilson, 2001). Most of the meta-analyses of writing intervention research have focused on treatments tested in true- and quasi-experimental studies (Bangert-Drowns, 1993; Bangert-Drowns, Hurley, & Wilkinson, 2004; Goldring, Russell, & Cook, 2003; Graham, 2006a; Graham & Harris, 2003; Graham & Perin, 2007a, 2007b; Hillocks, 1986).

Correspondence concerning this article should be addressed to Steve Graham, Peabody 328, 230 Appleton Place, Vanderbilt University, Nashville, TN 37203. E-mail: steve.graham@vanderbilt.edu

However, two of the meta-analyses also computed effect sizes for treatments tested via single subject designs (Graham, 2006a; Graham & Harris, 2003). These two reviews only examined a single treatment: teaching strategies for planning/revising. Consequently, the primary purpose of this article was to conduct a more extensive meta-analysis of single subject design writing interventions in order to identify effective writing practices for students in Grades 1–12.

Like true-experimental studies, single subject designs can be used to test whether a treatment is responsible for observed changes in performance. As Horner et al. (2005) noted, “Single-subject design is experimental rather than correlational or descriptive, and its purpose is to document causal or functional relationships between independent and dependent variables” (p. 166). Major threats to internal validity are controlled through within- and between-subjects comparisons, and external validity is enhanced through systematic replication. In single subject design studies, each participant serves as her/his own control, with performance prior to as well as during and/or after intervention repeatedly measured to establish performance patterns before treatment and comparison of performance patterns across experimental phases (e.g., baseline versus treatment). To establish experimental control, the independent variable or treatment is actively manipulated to determine its effects on the dependent measure(s) (Horner et al., 2005).

One manipulation (reversal) for establishing experimental control involves introduction and withdrawal of the treatment (e.g., a stable baseline pattern of performance is established, followed by introduction of treatment to determine whether it influences the dependent measure[s], followed by withdrawal of treatment to determine whether performance returns to or near baseline levels, followed by reintroduction of treatment to determine whether performance is again influenced).

A second manipulation (multiple baselines) involves the staggered introduction of the treatment. This can involve both within- and between-subjects comparisons. For example, after researchers establish a stable baseline pattern of performance for each participating student, treatment is implemented with one student to determine whether it influences the students’ performance in a predictable fashion. If the instructed student demonstrates the predicted pattern of change, while uninstructed students’ performance remains unchanged from baseline, then the treatment is implemented with the next student to determine whether the pattern described above is replicated. This systematic delay in introduction of the treatment continues until all students receive instruction.

With both of these manipulations, experimental control is established only if performance on the dependent measures is stable during each experimental phase (e.g., baseline and treatment) and there is no trend in the pattern of baseline performance in the direction predicted by the intervention. In addition, it is generally agreed that experimental control is not established until there are at least three demonstrations that the manipulation had the predicted impact. Thus, experimental control is established when the predicted covariation between the introduction of the treatment and changes in the dependent measure(s) are demonstrated through at least three demonstrations in an experiment.

In contrast to true- and quasi-experimental designs where the focus is on group performance, single subject design examines the

effectiveness of a treatment at the individual level (single subject design studies, however, typically include more than a single student). Considerable emphasis is placed on fully describing the participants, the context in which the investigation took place, and factors that influence participants’ performance prior to intervention (Horner et al., 2005). Such rich descriptions set the stage for determining the boundaries of generalization, but a basic tenet in single subject design research is that the generality of a treatment is not established in a single study. Instead, external validity is established by systematically replicating effects across multiple participants, locations, and researchers.

### Why a Meta-Analysis of Single Subject Design Studies Is Important

There are three reasons why it is advantageous to conduct a systematic, empirical, and full review of single subject design writing intervention research. First, the meta-analyses of true- and quasi-experimental investigations of writing interventions have identified only 12 interventions that improve the writing of elementary and secondary students (see Bangert-Drowns, 1993; Bangert-Drowns et al., 2004; Goldring et al., 2003; Graham, 2006a; Graham & Harris, 2003; Graham & Olinghouse, *in press*; Graham & Perin, 2007a, 2007b; Hillocks, 1986). These include (ranked according to the magnitude of their impact): teaching strategies for planning, revising, and editing; teaching written summarization; having students help each other carry out specific writing processes such as planning, drafting, or revising/editing; establishing specific goals for students’ writing; teaching handwriting, spelling, or typing to students; using word processing as a medium for writing; teaching students how to write more complex sentences through sentence combining activities; engaging students in inquiry as a means for developing ideas for writing; encouraging students to engage in prewriting activities to gather and organize possible writing content; establishing a process approach to writing; using writing as a tool for content learning; and having students study and emulate models of good writing. While the identification of these 12 treatments is an important accomplishment, these practices do not cover all aspects of learning to write. A meta-analysis of single subject design writing interventions has the potential to broaden current evidence-based recommendations.

Second, a meta-analysis of single subject design studies also has the potential to strengthen, undermine, or nuance the trust that can be placed in one or more of the 12 writing treatments identified as effective above. For example, converging evidence from true- and quasi-experimental studies as well as single subject design research would bolster the claim that a treatment was or was not effective, whereas conflicting evidence would undermine such a claim or foster a more nuanced conclusion. The need for additional evidence is also supported by the fact that only 4 of the 12 treatments identified above (teaching writing strategies, process writing approach, word processing, and using writing to learn) were based on 10 or more studies.

Third, most of the true- and quasi-experimental writing intervention research has been conducted with students representing the full range of writing ability in a typical classroom (Graham & Perin, 2007a). The only exceptions to this involve strategy instruction, word processing, and setting goals for students’ writing. In

contrast, single subject design studies often involve students' experiencing difficulty. Consequently, a meta-analysis of single subject writing intervention research has the potential to increase the number of identified evidence-based practices for struggling writers.

It is also important to establish that there is currently no comprehensive meta-analysis of single subject writing intervention studies. Graham and colleagues (Graham, 2006a; Graham & Harris, 2003) conducted meta-analyses of single subject design studies examining strategy instruction in planning, revising, and/or editing. The first of these reviews (Graham & Harris, 2003) only focused on a specific model of strategy instruction, whereas the second review (Graham, 2006a) concentrated on all single subject design studies in this area. In both reviews, teaching writing strategies had a positive impact on writing, providing additional support to the findings from true- and quasi-experimental studies (e.g., Graham & Perin, 2007a).

### The Current Meta-Analysis

The meta-analysis reported in this article draws on but greatly extends the two previous meta-analyses of single subject strategy instruction research in writing (Graham, 2006a; Graham & Harris, 2003). We not only broadened the review to include all writing practices tested via single subject design but conducted a broader search than Graham (2006a) or Graham and Harris (2003), resulting in the identification of some studies not included in their review. To reduce the likelihood of only identifying studies where positive effects were obtained (i.e., nonsignificant findings are rarely published in peer-refereed journals), we searched as broadly as possible, including studies published in journals as well as dissertations, theses, and book chapters.

The primary research question guiding this review was, Which writing practices tested via single subject design procedures are effective with students in Grades 1–12? Consistent with Graham and Perin (2007a), no conclusions were drawn about a treatment unless there were at least four studies with a conceptually similar outcome measure assessing its impact. Furthermore, we assessed the quality of each single subject design study included in this review, using quality indicators developed by Horner et al. (2005). This allowed us to identify strengths and weaknesses in the current body of single subject writing intervention research and temper conclusions about the effectiveness of a treatment based on the quality of the research.

The theoretical bases for many of the writing treatments in this review were grounded in behavioral theory. This is not surprising, as single subject design methodology grew out of behavioral work in the 1960s (Horner et al., 2005). Nevertheless, some treatments, such as strategy instruction, were influenced by cognitive (Hayes, 2000) and/or behavioral models, whereas the theoretical underpinnings of other treatments were unstated (e.g., word processing). Consequently, we draw no claims about the validity of specific theories.

### Method

#### *Location and Selection of Studies*

The strategies that we used to locate and select studies for this meta-analysis were influenced by five factors. First, studies were

included that involved students in Grades 1–12. This differed from Hillocks's (1986) comprehensive meta-analyses of true- and quasi-experimental writing intervention research that focused on students in Grade 3 to college, and Graham and Perin (2007a, 2007b), who concentrated on Grades 4–12. As noted earlier, our goal was to identify effective writing treatments for both elementary and secondary students.

Second, we included studies that were conducted with students attending regular public schools, private schools, alternative schools, summer programs, clinics, and residential centers. We cast a broader net than Graham and Perin (2007a, 2007b), who did not include studies conducted in special schools for persons with disabilities (e.g., residential centers), as we were especially interested in identifying writing practices that would be effective with struggling writers, including those with disabilities (we did not purposefully exclude any type of disability).

Third, we included only single subject designs with mechanisms for establishing experimental control (i.e., demonstrating a functional relationship between the independent and dependent variable). This included reversal and multiple baseline designs (described in the introduction) as well as alternating treatment and changing criterion designs. Alternating treatment designs involve the rapid alternation of two or more distinct treatments (with each treatment presented the same number of times) in a counterbalanced fashion to determine their impact on a single outcome measure. The treatments are alternated rapidly to reduce the possibility of carryover effects, and treatments are counterbalanced to eliminate order effects. We only included alternating treatment design studies that included a baseline (this is a recommended practice but is not absolutely essential). Baseline is established before introduction of the alternating treatments or by including it as one of the alternating treatment conditions (i.e., a no-treatment condition). Experimental control is established when a treatment repeatedly produces the predicted change in behavior in reference to baseline (whether this is a baseline established before alternating treatments or a no-treatment control included as one of the alternating treatments).

With a changing criterion design, the desired outcome during treatment is gradually and systematically increased or decreased for a specific behavior. After establishing a stable baseline pattern of performance, the researcher introduces the treatment (e.g., reinforcement) but divided into subphases, with two or more subphases requiring increased changes (if the desire is to improve the behavior; e.g., "Write 20 words," "Write 30 words") and at least one subphase requiring decreased changes (e.g., "Now write only 15 words"). Such changes are meant to gradually move the student toward the desired terminal goal (e.g., "Write 50 words") while demonstrating that it is treatment, and not maturation, that causes the change. Experimental control is established if the student's behavior matches or exceeds the predetermined criterion specified in each subphase of treatment.

Fourth, studies were included if they provided the data needed to calculate the effect size, percentage of nonoverlapping data (PND; this measure is described more fully later). This required that the data at each assessment point was provided either in graph or tabular form. If a study did not have such data for at least one writing measure, it was not included in this review. In addition, we did not include studies where baseline data were not collected. Nor did we include studies that focused solely on the teaching of

handwriting or spelling, as they typically do not examine whether such instruction impacts students' actual writing (Graham, 1999).

Fifth, we searched broadly to identify possible studies. This involved locating peer-refereed and nonrefereed studies from a variety of sources, including studies in prior meta-analyses (i.e., Graham, 2006a; Graham & Harris, 2003), journals, theses and dissertations, conference proceedings, and books. We searched broadly, going beyond published peer-refereed articles, to reduce the possibility of bias, as studies are rarely published in peer-refereed journals when they do not obtain positive treatment results.

A number of databases were searched during January 2007 for relevant studies, including ERIC, PsycINFO, ProQuest, Education Abstracts (i.e., Education Full Text), and Dissertation Abstracts. We ran multiple searches in these databases, pairing writing, composition, and narrative with the following terms: *dictation, genre, genre and instruction, goal setting, grammar, inquiry, mechanics, models, peer collaboration, peer planning, peer revising, peers, planning, revising, pre-writing activities, process writing, reinforcement, self-evaluation, self-monitoring, sentence combining, sentence construction, speech synthesis, spell checkers, strategy instruction, summary instruction, summary strategies, summary writing, technology, usage and mechanics, word processing, word processor, writer's workshop, and writing assessment*. These terms were also included in the search by Graham and Perin (2007a).

These same databases were searched to identify single subject design writing intervention research conducted by 11 prominent researchers in this area (e.g., K. Ballard, T. Glynn, and C. MacArthur). We also conducted a hand search of the following journals that frequently publish single subject design research: *Education and Treatment of Children, Educational Psychologist, Exceptional Children, Journal of Applied Behavior Analysis, Journal of Behavioral Education, Journal of Learning Disabilities, Journal of Special Education Technology, Learning Disabilities & Practice, Learning Disability Quarterly, and Remedial & Special Education*. Finally, the reference lists for all obtained articles were searched to identify relevant studies.

Using these search mechanisms, we collected 119 documents and found 88 studies that were suitable for this review. The most common reason for excluding a study was that it did not include a writing outcome measure. This occurred in 11 instances. Nine studies were eliminated because they did not apply a design where experimental control could be established, whereas 5 studies were excluded because they contained no baseline phase. Finally, 3 studies were omitted because the same data were published elsewhere, 2 did not provide the data needed to calculate PND, and 1 study included a combined writing/reading intervention.

### *Categorizing Studies Into Treatment Conditions*

First, each study was read and placed into a treatment identified in advance. These treatments corresponded to the descriptors used in the electronic searches. These categories were supplemented by two additional treatments common in behavioral research: reinforcement and direct instruction. Studies that did not fit neatly into one of these preidentified categories were held apart until all studies were read and sorted. At this point, the studies in each preidentified treatment were reread to determine whether the in-

tervention in each study represented the same general treatment. If this was not the case, they were placed with the studies that were not classified during the initial reading. All of the studies in the unclassified pile were read again, resulting in the construction of new treatments. The studies in these new treatments and any preidentified treatment where an additional study was placed were again reread to determine whether each intervention represented the same general treatment. As this process took place, we refined some initial treatment categories and eliminated others (when no studies tested that treatment).

At least one or more studies examined the effectiveness of the following 20 treatments (ordered from most to least frequently studied): strategy instruction for planning/drafting (25 studies), self-monitoring (8 studies), goal setting for productivity (7 studies), reinforcement (6 studies), prewriting activities (5 studies), sentence construction (5 studies), strategy instruction editing (5 studies), strategy instruction paragraph construction (5 studies), word processing (5 studies), teaching grammar/usage (4 studies), feedback on writing (4 studies), strategy instruction other (4 studies), strategy instruction revising (2 studies), direct instruction of a broad array of skills (2 studies), goal setting for grammar/sentence construction (2 studies), word processing plus (2 studies; these studies included word processing plus an additional support, for example, text read aloud by the computer), dialogue journals (1 study), direct teaching of self-regulation strategies (1 study), repeated writing (1 study), and verbal encouragement (1 study).

The most common treatment involved teaching strategies for carrying out specific aspects of the writing process. Instead of lumping these into a single category, we separated them into different categories depending on the processes emphasized. Most of these studies focused on teaching a genre-specific writing strategy for planning and drafting papers (stories, persuasive essays, and expository text), and this formed a single category. All of the planning/drafting strategies in these 25 investigations were taught using the Self-Regulated Strategy Development model (SRSD; see Harris & Graham, 1996, for a description of this teaching approach).

The other strategy instructional categories that we created concentrated on teaching strategies for writing paragraphs, editing only, or revising/editing. Since these investigations emphasized different processes (from each other and the strategy for planning/drafting studies), we created a category for each. Finally, a small number of strategy instructional studies did not fit neatly into any of these categories and were placed in a strategy instruction other category. Studies in this category included investigations where strategy instruction was combined with other practices (such as a token reinforcement system; Boyer, 1990), students were taught a summary writing strategy (Nelson, Smith, & Dodd, 1992), or the study did not assess students' independent use of the strategy (Li, 2000). Our decision to create multiple strategy treatments differed from Graham and Perin (2007a, 2007b), where all strategy studies were included in the same category.

We also differed from Graham and Perin (2007a, 2007b) in that we created two treatment categories for goal setting. The purpose of the goals in these two categories differed, as one set of goals was aimed at increasing productivity, and the other focused on grammatical correctness. It should be noted that we created two word processing treatment categories. This included word processing, which examined the effects of word processing and software

commonly bundled into such a program (e.g., spell checkers) as well as word processing plus, which included word processing plus programs like word prediction (Handley-More, Deitz, Billingsley, & Coggins, 2003) and speech synthesis programs that read written text aloud (Channon, 2004).

As noted earlier, we calculated only a summary statistic (mean PND) for treatments that included four or more studies with a conceptually similar outcome measure. Table 1 presents a definition for the 10 treatment categories that met this condition. We decided to adopt this criterion, as it was used by Hillocks (1986) in his seminal review and Graham and Perin (2007a, 2007b) in their more recent review. If reviewers use similar criterion, it is easier to make valid comparisons across reviews. We recognize, however, that small sample sizes are less reliable and must be interpreted more cautiously than a summary statistic based on a larger number of studies.

The decision to stress a conceptually similar outcome measure in computing a summary statistic also has precedence in the two prior comprehensive reviews of true- and quasi-experimental research (Graham & Perin, 2007a, 2007b; Hillocks, 1986). In those reviews, the focus was only on the outcome measure of writing quality (it was assumed that there would be less noise or error in the analyses, if the outcome measures were conceptually similar). With the single subject design studies reported here, researchers typically graphed just the measure that was most directly associated with the intervention (e.g., if the intervention was meant to increase writing output, then this variable was graphed). Thus, there was no single outcome measure for most of the studies in this review. For half of the treatments described in Table 1, there were at least four or more studies that graphed writing productivity (number of words and sentences). These treatments were goal setting for productivity, reinforcement, self-monitoring, strategy instruction for planning/drafting, and word processing. Two treatments (prewriting and strategy instruction for planning/drafting) met the four study criteria for quality of writing (as measured with holistic rating scales; see Graham & Perin, 2007a), whereas an-

other two treatments (strategy instruction for planning/drafting and strategy instruction for paragraph construction) met it for elements (basic structural elements of a genre or writing task, such as story parts). Sentence construction, strategy instruction for editing, and teaching grammar/usage had four or more studies that graphed number of complete sentences, errors corrected, and grammar errors, respectively.

### *Coding of Study Features*

*Descriptive information.* For each study that met the established criteria, the following 10 pieces of information were collected and coded: type of design (i.e., withdrawal design, multiple-baseline design, alternating treatment design, and changing criteria design), number of participants, type of writers (i.e., full range of writers in a typical classroom, above average writers only, average writers only, struggling writers only, and English language learners), grade of study participants, age of study participants, disability status of each participant (i.e., attention-deficit/hyperactivity disorder [ADHD], behavior disorder, emotional and behavior disorder, emotionally disturbed, learning disability, mild language delay, mild mental retardation, other health impairment, orthopedic impairment, speech and language delay, visual impairment, and Section 504), race/ethnicity of participants (i.e., African American, American Indian, Caucasian, Hispanic, Arab, or Other), geographical location of study (i.e., suburban, rural, or urban), person providing instruction (i.e., teacher or member of research team), and written description of independent variable (coded as one of the 20 treatment categories established in the previous section).

*Quality indicators.* In addition to this descriptive information, each study was evaluated to see whether it met 11 specific indicators of study quality proposed by Horner et al. (2005) for single subject design research. Some of these quality indicators were based in part on the descriptive information collected and coded above, but others required the collection of additional information.

Table 1  
*Summary of Evidence-Based Practices for Teaching Writing*

Treatment category	Definition
Strategy instruction: Planning/drafting	Students were taught strategies for planning, drafting, and/or revising stories, persuasive essays, and/or expository essays. This included modeling of the strategy and guided practice to facilitate independent use of it.
Teaching grammar/usage	Students were taught grammar and usage skills via well-sequenced and highly focused instruction.
Goal setting for productivity	Students were provided or set an explicit goal to write more.
Strategy instruction: Editing	Students were taught a strategy for editing their papers. This included modeling of the strategy and guided practice to facilitate independent use of it.
Word processing	Students used word processing as their medium for writing.
Reinforcement	Students received praise, public recognition, or tangible items contingent on writing improvement(s).
Prewriting activities	Students used graphic organizers, including story maps and outlines, for generating ideas prior to writing.
Sentence construction	Students were taught sentence skills through either sentence combining or a strategy for writing sentences.
Strategy instruction: Paragraph construction	Students were taught a strategy for writing a paragraph. This included modeling of the strategy and guided practice to facilitate independent use of it.
Self-monitoring	Students self-monitored either their on-task behavior, writing productivity, or writing quality, and the results of their performance was displayed.

The score for each indicator ranged from 0 to 1 (with a score of 1 indicating that the quality indicator was met), and all scores for a study were summed to obtain a total quality score.

The quality indicator, participant description, was based on five or six pieces of information, depending on whether students with disabilities were included in the study. A study received a score of 1 on this indicator, if information was provided on participants' (a) ages or grades, (b) gender, (c) socioeconomic status, (d) ethnicity, (e) writing achievement at the start of the study, and when appropriate (f) disability status. The score for this indicator was calculated by assigning 1 point for each of these items if they were reported, and then dividing by either 5 or 6, depending on whether students with disabilities were included in the study.

A score of 1 was awarded if the researcher described the procedures for determining how students were selected to participate in the study (this needed to be done in enough detail so that another researcher could replicate these procedures). A score of 1 was also assigned if the location where instruction took place was described in enough detail so that it could easily be visualized. For each indicator, a score of 0 was awarded if the criterion was not met.

For the quality indicator, operationally defining dependent variables, we examined whether the procedures for scoring dependent variables (that were graphed) were described in enough detail to allow other researchers to use these measures. If all dependent measures were defined in this fashion, a score of 1 was assigned. A score of 0 was assigned if no dependent measures met this criterion. A score of .50 was awarded if at least one of the dependent variables met this criterion.

The quality indicator, interrater reliability of graphed dependent variables, was assessed by calculating the proportion of dependent measures that were scored reliably. If reliability for all dependent measures equaled or exceeded .60, a score of 1 was awarded. A score of 0 was awarded if none of the dependent variables met this criterion. If the reliability for some but not all dependent variables was .60 or higher, then the number of dependent measures meeting criterion was divided by total number of dependent variables. Researchers used different means to calculate reliability (ranging from percentage agreement to correlation coefficients).

For the quality indicator, multiple baseline data points, we examined each baseline to determine whether it had three or more data points. A score of 1 was assigned if all baselines met this criterion, whereas a score of 0 was assigned if no baselines met it. If some but not all baselines met this criterion, then the proportion that met it was calculated. The exact same procedures were used to score the quality indicator, multiple intervention data points.

The remaining four quality indicators (treatment description, fidelity of treatment, testing procedure descriptions, and social validity) received a score of either 1 or 0. A score of 1 was awarded for each of the following: a treatment was described in enough detail so that it could be applied by others, the researcher collected and reported data that demonstrated fidelity of treatment (treatment was delivered as intended), enough detail (e.g., directions) was provided so that other researchers would be able to administer the writing assessments, and data on the social validity of the treatment were collected (as suggested by Kennedy, 2002, this could include questioning students, teachers, or others about the social validity of the treatment or a demonstration that treat-

ment gains were maintained for 3 or more weeks following instruction).

In addition to these 11 quality indicators, we also examined whether experimental control was established. This is critical to establishing a functional relation between the independent and dependent variables. Experimental control was established if there were at least three demonstrations in a study of an experimental effect that met these criteria: (a) the last three data points in baseline established a stable pattern of behavior (i.e., the last three data points fluctuated by no more than 20% from the highest score of the three data points), (b) there was no trend in baseline performance in the direction predicted by the treatment, (c) and treatment had the predicted impact on behavior. To determine whether treatment had the predicted impact on behavior (letter *c* above), 50% or more of the treatment data points had to exceed the strongest baseline score.

In determining whether experimental control was established, it was necessary to customize the third criterion above to the four different single subject designs included in this review. For withdrawal designs, treatment had the predicted impact on behavior when 50% or more of the data points in the first introduction of the treatment ( $B_1$ ) surpassed the strongest initial baseline score ( $A_1$ ) and strongest score when treatment was withdrawn and the second baseline was initiated ( $B_2$ ). For multiple baseline designs, 50% or more of the treatment data points had to exceed the strongest baseline score, and there could be no corresponding improvement or trend toward improvement for each baseline that had not received treatment yet. For alternating treatment designs, 50% or more of the treatment scores for a specific treatment had to exceed the strongest score from baseline. This included the strongest score from either a baseline established before treatments were alternated and/or baseline scores collected as an alternating condition (i.e., no treatment). For changing criterion designs, all of the treatment data points from the first subphase of treatment had to fall within 20% of the stated goal for that subphase, with this same criterion applied to subsequent subphases.

**Reliability.** To establish the reliability of scoring procedures, 20% of the studies ( $n = 18$ ) were randomly selected and rescored. The second reader was trained and scored all 18 studies independent of Leslie Rogers. Interrater reliability was established for each scoring procedure separately. The scoring procedures were reliable, as percentage of agreement ranged from 89% to 100%, with a mean percentage of agreement across all variables of 96%.

### *Calculation of Effect Sizes*

In order to assess overall treatment effects, we employed a nonparametric approach to meta-analysis and calculated the percentage of nonoverlapping data points between baseline and treatment phases: referred to as PND (Scruggs, Mastropieri, & Casto, 1987). PND is the percentage of data points in treatment that represent an improvement over the most positive value obtained during baseline. As recommended by Scruggs, Mastropieri, Cook, and Escobar (1986), PND was not calculated when ceiling or floor levels were evident during baseline (depending on the intended direction of the outcome variable), as there was no room for treatment effects to be realized.

For each study, we calculated a separate PND for each measure that provided the needed information. PND for a specific measure

in a study was calculated by first obtaining PND for each baseline treatment comparison (or changing condition) and then calculating an average PND across all relevant changing conditions for that measure. When possible, we calculated a PND for treatment, maintenance, and generalization for each measure, as we were interested not just in immediate effects but in the impact of the treatment over time as well as transfer effects to other situations. A PND calculated for treatment involved comparing scores during treatment, immediately following treatment, or both to the strongest baseline score for each changing condition in the study. A PND calculated for maintenance involved comparing a student's scores collected 3 weeks or more after treatment ended to the strongest baseline score for each changing condition in the study. A PND for generalization (typically to another genre or setting) involved comparing a student's generalization scores during or after treatment to the strongest generalization score during baseline for each changing condition in the study.

When there were four or more studies of a treatment that included a conceptually similar outcome measure, we calculated a mean, median, and range of PNDs for that measure across studies (confidence intervals were not calculated as PND lacks a known sampling distribution; Parker, Hagan-Burke, & Vannest, 2007). When possible, we calculated these three indices (mean, median, and range) for treatment, maintenance, and generalization. PND was interpreted using criteria proposed by Scruggs et al. (1986): PND greater than 90% is a large effect, PND between 70.1% and 90% is a moderate effect, PND between 50.1% and 70% is a low or small effect, and PND 50% or below is classified as not effective.

To avoid overinflating the importance of a single study, it is recommended that a single effect size be calculated for each study (Lipsey & Wilson, 2001). Although we computed more than one PND for many studies, this basic concept was followed here. For all but one of the treatments, only one effect size from each study was used to calculate summary PNDs. In all of these instances, we were only able to calculate a summary PND for a single measure for each treatment. The only exception involved the treatment of strategy instruction for planning/drafting. Almost all of the studies in this category had a conceptually similar outcome measure that was graphed (i.e., elements), but there were also enough studies that conjointly graphed productivity and writing quality that we were able to calculate a separate summary PND for these measures too. We decided to present a summary PND for these measures separately, as it made little sense to develop a single summary PND combining all three measures or simply ignore two of them. The summary PND for a measure was never based on more than one effect size from a single study, however. The same was true when a summary PND was computed for treatment, maintenance, or generalization.

PND was calculated for all studies by Leslie Rogers, and reliability was established by a second rater who calculated PND for 18 randomly selected studies. Reliability was .99.

Why did we decide to use PND over other methods for calculating effect sizes for single subject design studies? First, as Scruggs and Mastropieri (1998) noted, single subject design effect sizes created by subtracting mean baseline performance from mean treatment performance and dividing by baseline (or the pooled) standard deviation (much like Cohen's *d*) do not take into account the within-subject nature of the data and can result in effect sizes

that are idiosyncratic and meaningless (e.g., when we have used this method for SRSD single subject design studies in writing, the effect sizes are typically 3.0 and higher; they average just over 1.0 in true- and quasi-experimental studies; Graham & Perin, 2007a). Other alternative methods, such as the regression effect size method (which examines the proportion of student score variance explained by phase differences), also possess limitations that made them less suitable for our analysis (see Scruggs & Mastropieri, 1998, for a discussion of different approaches). For example, the parametric assumptions (normality, equal variance, and serial independence of data) underlying techniques such as the regression effect method are not commonly met in single subject design studies (PND is not bound by these parametric assumptions; see Parker et al., 2007). Second, we would have had to eliminate many studies from this review if the regression approach were applied, as it was not possible to determine the exact scores for each data point from graphs in many studies (it was possible, however, to compute PND, as it is only necessary to establish that one score was greater than another). Third, PND was the most commonly used measure in previous meta-analyses of single subject writing intervention research; Graham, 2006a; Graham & Harris, 2003), making it easier to compare findings across reviews.

## Results

Table 2 presents basic information about the individual studies that tested the effectiveness of the 10 treatments that included four or more studies with a conceptually similar outcome measure (see Table 1 for a description of these treatments). This includes information about study design, participants (number, type of writer, grade, age, and race/ethnicity), geographic location, overall quality of study (based on the 11 quality indicators), whether experimental control was established, as well as the PNDs for specific measures. The Appendix includes information about studies that were included in treatments with three or less studies with a conceptually similar outcome measure. Table 3 presents summary PNDs (mean, median, and range) for each of the treatment categories included in Table 2, whereas Table 4 presents summary PNDs for the treatment, strategy instruction for planning/drafting, by type of genre (story versus expository).

Table 5 presents the average quality score for studies in each of the 10 treatments included in Table 2. The total quality score was the sum of the scores for the 11 quality indicators (e.g., participant description and participant selection). For each treatment, we also report the percentage of studies where each quality indicator was met. This same information is presented cumulatively for all studies included in the 10 treatments, providing a general indication of the quality of the single subject design intervention studies on which our findings are based.

Before examining individual treatments, we first offer some comments on the overall quality of single subject design writing intervention studies. As can be seen in Table 5, almost all studies quantified dependent variables, established reliability of variables, collected three or more data points in baseline as well as intervention, and adequately described the intervention. However, participant description and selection were only adequately described in about one half of the studies, and an adequate description of the

*Note.* Production includes number of words, ideas, and/or T-units, as well as number of assignments completed. N = number of studies; FR = full range; SW = struggling writer; PND = percentage of nonoverlapping data points; TX = scores during treatment; TX/POST = scores during treatment as well as immediately after treatment (less than 3 weeks after treatment ended); MAINT = maintenance (3 or more weeks after treatment ended); GEN = scores for generalization probes.

physical location of the study was only offered about one third of the time (these findings raise concerns about external validity). Likewise, fidelity of treatment was established in less than one half of the studies (possibly because this has not been stressed until recently) but adequate description of testing procedures and the establishment of social validity of the treatment occurred in about two third of the studies.

The findings for each of the 10 treatments in Table 1 are presented next. Each treatment is presented separately using a common format. First, information on studies testing the treatment is summarized. This is followed by the summary PND statistics (mean, median, and range) and interpreting these statistics in light of the quality of the studies on which they were based (the 11 quality indicators in Table 5 and the establishment of experimental control; see Table 2).

#### Strategy Instruction: Planning/Drafting

Twenty-five studies examined the effectiveness of teaching strategies for planning/drafting specific types of text (see Table 2). As noted earlier, all of these investigations used the SRSD model (Harris & Graham, 1996) to teach these strategies. A common component in most of the planning/drafting strategies taught was that students used specific features of the target genre (e.g., characters, location, time, goals of characters, actions, ending, and reactions for stories) to help them generate and organize possible writing ideas. Planning/drafting strategies focused on stories (e.g., Adkins, 2005; Albertson, 1998; Albertson & Billingsley, 1997), persuasive text (e.g., De La Paz & Graham, 1997; Lienemann, 2006; Mason & Shriner, 2008), and expository essays (e.g., De La

Note. Maximum number of quality points = 11. N = number of studies; DV = dependent variable; Interv. = intervention.

Paz, 1999, 2001; Mason, Snyder, Sukhram, & Kedem, 2006), and they are grouped in this fashion in Tables 2 and 3.

Twenty-one of the 25 studies had a common outcome measure: elements. These structural elements included the basic parts of a composition that students generated ideas for when planning. In 18 of the 21 studies that assessed elements, maintenance effects (3 or more weeks after the termination of treatment) for elements were assessed. In addition four studies examined generalization of elements from one genre to another (i.e., story to personal narrative). Separate PNDs (mean, median, and range) were computed for each of these conditions.

There were 108 students (almost equally divided between boys and girls) in the 21 planning/drafting intervention studies that included a measure of elements (see Table 2). These youngsters were in Grades 2–8, and most of them were struggling writers (18 of the 21 studies). There were a variety of students with disabilities, but the most common group was children with learning disabilities (other students with disabilities included students with ADHD, emotional and behavioral disorders, mild language delay or speech/language impairment, and mild mental retardation). In one study (Albertson & Bilingsley, 1997), gifted students were the target of instruction (typical writers were the focus in the other two studies). Race/ethnicity was reported in 15 studies, and the majority of students were Caucasian (55%; 48/87), followed by African American (37%; 32/87), Arab (5%; 4/87), Hispanic (2%; 2/87), and Asian (1%; 1/87). When locale was reported ( $n = 16$  studies), suburban was the most common location (56%; 9/16), followed by rural (25%; 4/16) and urban settings (19%; 3/16). Researcher most commonly delivered instruction (81%; 17/21), and all of the studies employed multiple-baseline designs. It is also important to note that the 18 studies that assessed maintenance of elements had the same basic characteristics described above, but the four studies that assessed generalization of elements to a different genre only included struggling writers in Grades 2, 3, 5, and 6.

Teaching students a planning/drafting strategy had a large impact on increasing the number of basic genre elements in their writing, and this effect maintained over time (see Table 3). Median PND for treatment and maintenance was 100% in both cases. Mean PND was 96% (range = 100% to 67%) and 90% (range = 100% to 25%), respectively. Teaching these strategies also had a moderate impact on enhancing the generalization of elements from an instructed genre to an uninstructed one. Median PND was 86%, and mean PND was 85% (range = 100% to 67%).

Ten of the 25 planning/drafting strategy instructional studies assessed productivity (i.e., number of words written) during or immediately after instruction (mostly struggling writers in Grades 2–8 but also typical writers in Grades 6–8), with 7 of these studies assessing maintenance of productivity (focusing almost exclusively on struggling writers in Grades 2–8, with some typical writers in Grades 7 and 8). Moreover, 5 of the 25 studies assessed and graphed quality of students writing immediately following instruction (this involved students in Grades 2–4 and Grades 7 and 8 with a mixture of struggling and typical writers).

Teaching students a planning/drafting strategy had a large impact on productivity and quality during and/or immediately following instruction (see Table 3). Median PND for productivity and quality were 95% and 99%, respectively. Mean PND was 91% (range = 100% to 68%) and 99% (range = 100% to 97%), respectively. In addition, students generally maintained productiv-

ity gains, as median and mean PND were 100% and 86%, respectively (range = 100% to 33%).

We also examined the impact of strategy instruction for planning/drafting on writing genres. We computed separate PNDs for stories and expository writing (we combined persuasive text and expository essays for this second category). As can be seen in Table 4, this treatment had a large effect on both genres in terms of elements and productivity (all median and mean PNDs were 91% or greater). The only exceptions involved maintenance of elements for expository writing (mean PND = 89%) and maintenance of productivity for stories (mean PND = 79%).

The studies examining the teaching of strategies for planning/drafting were of high quality (on average, 82% of the quality indicators were met in all studies; see Table 5). The only quality indicator that was not met in at least 50% of the studies was description of the setting where instruction took place. Most importantly, experimental control was established in all but three of the studies that were used to compute summary PNDs for elements, productivity, or quality.

In summary, strategy instruction was effective in enhancing the number of elements, written output, and quality of students' writing, and the effects for elements and productivity were maintained over time. In addition, when transfer to a different genre was measured, positive effects were also obtained. For the most part, these findings generalize best to struggling writers in Grades 2–8 but are also valid for typical writers in Grades 4–8. Considerable confidence can be placed in these findings, as studies were of high quality and experimental control was established in almost all of them. The only concern involves failure for all but a few of the studies to adequately describe the setting where instruction took place. This narrows any generalization about conditions under which this treatment is effective.

### *Teaching Grammar/Usage*

Four studies evaluated the effectiveness of teaching grammar/usage (see Table 2). Teaching grammar/usage included peers directly teaching capitalization skills to classmates (Campbell, Brady, & Linehan, 1991) to teachers directly teaching adverbial phrases and possessives (Dowis, 1991; Dowis & Schloss, 1992) to how to correct capitalization, subject/verb agreements, conjunctions, incomplete sentences, and run-on sentences (Hermann, Semb, & Hopkins, 1976). All four studies included a similar outcome measure that focused on correct use of grammar. In all instances, the grammar measure assessed grammar skills students were taught during treatment.

There were 30 students in the four grammar/usage studies (see Table 2). The participants were all struggling writers in Grades 2, 5, and 6. In all but one of the studies (Hermann et al., 1976), the students were either learning disabled or classified as having a mild mental retardation (1 child). In the three studies that provided information on gender, boys and girls were represented almost equally.

In the two studies that provided information on race/ethnicity, most students were Caucasians (71%; 5/7) followed by African Americans (29%; 2/7). With the exception of the one study where peers delivered instruction (Campbell et al., 1991), teachers were the instructors. The effectiveness of grammar/usage instruction was tested via multiple-baseline and withdrawal designs.

Directly teaching grammar/usage had a moderate effect on improving grammar skills (see Table 3). The median PND was 84%, whereas the mean PND was 83% (range = 88% to 75%). On average, the four studies in this category met approximately 75% of the 11 quality indicators (see Table 5). None of the studies established treatment fidelity, but experimental control was established in three of the four investigations (see Table 2).

In summary, directly teaching grammar/usage had a positive impact on the grammar skills of struggling writers in Grades 2, 5, and 6. Studies were generally of high quality, but there was uncertainty that the treatment was delivered as intended in any of the studies.

### *Goal Setting for Productivity*

Seven studies were located that examined the impact of setting goals (see Table 2). Goal setting in these studies ranged from teachers encouraging students to exceed their previous publicly posted writing performance and receiving immediate feedback on their success (Van Houten, Morrison, Jarvis, & McDonald, 1974) to teachers setting a goal for how much students would write, with students monitoring their success in meeting the goal, and placing a star on a public chart if the goal was met (Wolfe, 1997). All of the studies included a common outcome measure: productivity. Productivity focused on amount of text produced and included the following measures: (a) number of words (Hopman & Glynn, 1989; Van Houten & McKillop, 1977; Van Houten et al., 1974; Wolfe, 1997), (b) number of words plus number of adjectives (Weygant, 1981), (c) number of writing lessons completed (Seabough & Schumaker, 1994), and (d) percentage of writing assignments completed (Kastelen, Nickel, & McLaughlin, 1984).

The seven goal setting studies included 129 students in Grades 2–5 and 8–12 (see Table 2). In the four studies that provided information on gender, the majority of participants were boys (85%, 17/20). Only one study reported any information on race/ethnicity (i.e., Weygant, 1981; all participants were Caucasian). The participants in four studies were youngsters with learning disabilities or other struggling writers, whereas youngsters in the remaining investigations represented a full range of abilities. Two of the studies were conducted in urban schools; the other five studies did not provide information on locale. In four studies, the instructor was the students' teacher, while researchers provided instruction in the other three studies. A variety of different designs were used to assess the effectiveness of goal setting for productivity, including changing criterion, multiple-baseline, and withdrawal designs.

Depending on which measure of central tendency, mean or median, was used to summarize the overall impact of the treatment, goal setting for productivity had a large to moderate effect (see Table 3). The median PND was 91%, whereas the mean PND was 79% (range = 100% to 26%).

On average, the seven studies in this category met approximately 75% of the 11 quality indicators (see Table 5). Less than one half of the studies, however, adequately described participants, selection of participants, or the physical setting for the treatment. A similar problem occurred in terms of establishing fidelity of treatment or collecting data on social validity. In addition, only three of the seven studies achieved experimental control (see Table 2).

In summary, goal setting had a large to moderate effect on increasing writing productivity of students in Grades 2–5 and 8–12 (this includes struggling and regular writers). Although studies were generally of high quality, just three of the seven studies established experimental control. Furthermore, failure to adequately describe participants, settings, and selection procedures in a majority of studies narrows generalizations about whom and under what conditions this treatment is effective. There was also uncertainty, at least in some studies, that the treatment was delivered as intended, and it was unclear whether teachers and students valued the treatment.

### *Strategy Instruction: Editing*

Five studies examined the effectiveness of strategy instruction for editing (see Table 2). The editing strategies used in these studies ranged from an editing strategy developed as part of the University of Kansas strategy curriculum (Beals, 1983; Schmidt, 1983; Schumaker et al., 1982; Scott, 1993) to an editing strategy designed to help students use spell checkers when editing (McNaughton, Hughes, & Ofiesh, 1997). All of the studies included a common outcome measure: errors corrected. Errors corrected ranged from spelling errors corrected (McNaughton et al., 1997) to the correction of a broad range of errors (e.g., spelling, usage, and punctuation).

There were 32 participants in the five editing strategy instruction intervention studies (see Table 2). These youngsters were in Grade 4 and Grades 8–12. Each of the studies included struggling writers with learning disabilities, but one study primarily involved students representing the full range of writing abilities (Beals, 1983). Most of the participants were boys (72%; 23/32). When race/ethnicity was reported (three studies), the majority of students were Caucasian (65%; 13/20), followed by African Americans (35%; 7/20). Studies occurred in a variety of locations (two urban, one suburban, one rural, and one not reported). Teachers taught the editing strategy in 60% of the studies, and effectiveness was evaluated in all studies using multiple-baseline designs.

Depending on which measure of central tendency, median or mean, was used to summarize the overall impact of the treatment, teaching an editing strategy had a large to moderate effect on correcting errors in writing (see Table 3). The median PND was 100%, whereas the mean PND was 84% (range = 100% to 50%).

The researchers met most of the quality indicators in studies examining editing strategy instruction (72%), but more than one half of the studies failed to adequately describe participants or the setting where instruction took place (see Table 5). Testing procedures were not adequately described in a majority of studies, nor was treatment fidelity. Experimental control was only achieved in two of the five studies (see Table 2).

In summary, teaching an editing strategy had a large to moderate impact on decreasing errors in the writing of students in Grade 4 and Grades 8–12 (struggling writers and regular writers). Although studies were generally of high quality, some caution must be applied in interpreting this finding, as only two studies (out of five) established experimental control. In addition, failure to adequately describe participants and settings in a majority of studies narrows generalizations about whom and under what conditions this treatment is effective. There was also some uncertainty in a

majority of the studies that the treatment was delivered as intended.

### *Word Processing*

Five studies evaluated the effectiveness of word processing (see Table 2). Word processing in these studies ranged from students using word processing to write versus handwriting (Brigman, 1994; Burnett, 1984; Christensen, 1993; Handley-More et al., 2003) to students using word processing with a reminder to use the editing features of word processing software (Jones, 1985). Four of the studies used a similar outcome measure: productivity. Productivity included (a) total number of words (Christensen, 1993; Jones, 1985), (b) total number of words used per session (Brigman, 1994), and (c) total number of words per minute (Handley-More et al., 2003).

There were 27 students in the four word processing studies that assessed writing productivity. All of the students were struggling writers in Grades 1, 4, and 5. In one study, these struggling writers were learning disabled (Handley-More et al., 2003), and in another investigation, they were gifted underachievers (Christensen, 1993). Two of every 3 students in these four studies were male, and the studies occurred in urban, suburban, and rural locations. Race/ethnicity was reported in two studies, and the majority of these participants were Caucasian (83%; 15/18) followed by African Americans (17%; 3/18). Teachers were the instructors in two studies, and researchers were the instructors in the other two investigations. The effectiveness of word processing on productivity was tested via alternating treatment, multiple-baseline, and withdrawal designs.

Word processing had a moderate effect on increasing students' productivity (see Table 3). The median PND was 75%, whereas the mean PND was 70% (range = 100% to 29%). On average, the four studies in this category met close to 70% of the 11 quality indicators (see Table 5). None of the studies, however, established treatment fidelity, and less than one half of them adequately described the setting where instruction took place or assessed social validity. Experimental control was established in one half of the studies.

In summary, word processing had a positive impact on increasing productivity of struggling writers in Grades 1, 4, and 5. Some caution must be exercised in interpreting this finding, as experimental control was only established in 50% of studies. Failure to adequately describe the setting in more than one half of studies narrows any generalization about the conditions under which this treatment is effective. There was also uncertainty in all of the studies whether the treatment was delivered as intended. It was unclear whether teachers or students valued this treatment.

### *Reinforcement*

Seven studies examined the effectiveness of using reinforcement to enhance writing performance (see Table 2). Reinforcement in these studies included teacher praise for using different parts of speech in stories (Blase-Maloney, Jacobson, & Hopkins, 1975), obtaining reinforcement through public posting of writing performance (Ballard & Glynn, 1975), and receiving group reinforcement for including a certain number of words, different words, and new words in compositions (Brigham, Graubard, & Stans, 1972).

Four of the studies included a common outcome measure: productivity. Productivity measures in these studies included number of sentences, number of words, number of different types of words, and number of different sentence beginnings produced during writing (Ballard & Glynn, 1975; Blase-Maloney & Hopkins, 1973; Blase-Maloney et al., 1975; Brigham et al., 1972).

There were 60 students in Grades 3–6 in the four studies examining reinforcement (see Table 2). The participants' disability status, gender, and race/ethnicity were not reported in any study. Only two of the studies provided information on type of writer (Brigham et al., 1972, worked with struggling writers, whereas students in Ballard and Glynn, 1975, represented the full range of writing abilities). Likewise, only two studies specified location (Ballard & Glynn, 1975, were in a rural location, while Blase-Maloney et al., 1975, were in an urban school). Teachers delivered the treatment, and multiple-baseline designs were used in all studies.

Reinforcement had a large effect on students' writing productivity (see Table 3); the median and mean PND were 100% and 96%, respectively (range = 100% to 84%). The overall quality of reinforcement studies was not strong (see Table 5). None of the studies established treatment fidelity, and less than one in three studies collected social validity information. In addition, adequate descriptions of participants, settings, or selection processes were rare. Finally, only two of the four reinforcement studies that assessed productivity established experimental control (see Table 2).

In summary, reinforcement had a large impact on increasing the writing productivity of students in Grades 3–6 (both struggling and regular writers). Caution must be applied in interpreting this finding, as studies were generally of low quality, and only two (out of four) studies that assessed productivity established experimental control. Failure to adequately describe participants, settings, and selection procedures in a majority of studies narrows generalizations about whom and under what conditions this treatment is effective. There was uncertainty that the treatment was delivered as intended, and it was unclear whether teachers and students valued it.

### *Prewriting Activities*

The effectiveness of five prewriting activities was examined in four publications. The prewriting activities included using a computer prewriting outline to generate and organize information (Channon, 2004), learning to use a graphic organizer for generating ideas prior to persuasive writing (Thanhouser, 1994), and learning to use a story web for generating ideas prior to writing (Zipprich, 1995). Four prewriting comparisons in three studies (Channon, 2004; Thanhouser, 1994; Zipprich, 1995) included a common measure: writing quality. Quality was assessed using a holistic measure (see Graham & Perin, 2007b).

There were 16 students in the studies that examined the impact of prewriting strategies on the quality of writing (see Table 2). Participants were in Grades 3–5 (Zipprich, 1995), 8 (Channon, 2004), and 12 (Thanhouser, 1994). All of the students in these studies were struggling writers with learning disabilities. The majority of the youngsters in these studies were male (94%; 15/16) and Hispanic (50%; 8/16). The remaining students were Caucasian (44%; 7/16) or African Americans (6%; 1/16). In all but one case, the intervention was delivered by the students' teacher. Two of the

three studies indicated geographic location, which were urban and suburban schools, respectively. The effectiveness of prewriting in the three studies was assessed via alternating treatment and multiple-baseline designs.

The median and mean PND for prewriting were similar: 55% and 52%, respectively (range = 84% to 13%). Thus, prewriting had a small effect on improving writing quality.

The researchers met most of the quality indicators in studies examining prewriting activities (73%), but less than one half of the studies adequately described participant selection, established treatment fidelity (this was not done in any study), or assessed social validity (see Table 5). Experimental control was only achieved in one of the four comparisons that assessed writing quality (see Table 2).

In summary, prewriting activities had a small impact on improving the quality of writing produced by struggling writers in Grades 3–5, 8, and 12. Although studies were generally of high quality, caution must be applied in interpreting this finding, as only one comparison (out of four) established experimental control. In addition, the value of the treatment to teachers and students was unclear, and there was uncertainty that the treatment was delivered as intended.

### *Sentence Construction*

Five studies examined the effectiveness of teaching sentence construction skills (see Table 2). Sentence construction in these studies included teaching strategies for writing different types of sentences (Beals, 1983; Eads, 1991; Johnson, 2005; Schmidt, Deshler, Schumaker, & Alley, 1988; these strategies were developed as part of the University of Kansas strategy curriculum) and teaching students how to combine simpler sentences into more complex ones (First, 1994). All of the studies included a common measure: complete sentences. Complete sentences were measured by calculating the percentage of complete sentences independently written by students.

There were 64 participants in the five sentence construction studies (see Table 2). These youngsters were in Grades 6–8 and 10–12, and the studies included more boys than girls (66%; 42/64). In all studies, there were students with disabilities (mostly learning), but two studies focused mainly on students representing the full range of writing ability (Beals, 1983; Johnson, 2005). Four studies provided information on race/ethnicity; the majority of students were Hispanic (47%; 26/55), followed by Caucasian (44%; 24/55), African American (7%; 4/55), and Hispanic and African American (2%, 1/55). In the three studies that specified locale, they were evenly split between urban, suburban, and rural locations. In all cases, instruction was delivered by teachers, and multiple-baseline designs were used to test the effectiveness of teaching sentence skills.

Teaching sentence construction was an effective treatment (see Table 3). The median PND was 83%, whereas the mean PND was 86% (range = 100% to 78%). However, none of the studies established experimental control (see Table 2), and the overall quality of studies was poor (on average, each study only met 61% of the 11 quality indicators; see Table 5). More than one half of the studies did not meet the following criteria: participant selection, physical description of setting, fidelity of treatment, and testing procedure description.

In summary, sentence construction was an effective practice in increasing the percentage of complete sentences produced by students in Grades 6–8 and 10–12 (for struggling and regular writers). Caution must be exercised in interpreting this finding, as the research in this area was particularly weak.

### *Strategy Instruction: Paragraph Construction*

Five studies examined the effectiveness of teaching students strategies for constructing paragraphs. These five studies were included in four publications (Dowell, Storey, & Gleason, 1994; Moran, Schumaker, & Vetter, 1981; Sonntag & McLaughlin, 1984; Wallace & Bott, 1989). Paragraph construction strategies ranged from teaching students strategies for organizing and/or writing expository paragraphs (Moran et al., 1981; Sonntag & McLaughlin, 1984; Wallace & Bott, 1989) to teaching students how to write descriptive paragraphs (Dowell et al., 1994). A conceptually similar outcome measure, writing elements, was used in four of the examinations. Writing elements for paragraphs involved determining whether basic parts of a paragraph (e.g., topic sentence and concluding sentence) were evident and/or correctly used.

There were 18 students in Grades 8–9 in the four strategy instruction for paragraph studies where elements were assessed (see Table 2). Two thirds of these students were struggling writers with learning disabilities, whereas the remaining students represented the full range of writing ability. In the three studies where gender was reported, 67% of students were boys. No information on race/ethnicity was provided in any study. Two of the studies took place in a suburban location, with one study conducted in an urban school (no location was given for the fourth study). In all instances but one study (Wallace & Bott, 1989), teachers taught the strategies. Only multiple-baseline designs were used to test the effectiveness of this treatment.

Teaching strategies for writing paragraphs had a large and positive impact on the schematic structure (i.e., elements) of students' paragraphs (see Table 3). The median PND was 100%, whereas the mean PND was 97% (range = 100% to 89%). However, studies were of poor quality (on average, only 58% of the 11 quality indicators were met; see Table 5). More than one half of the studies did not meet the following criteria: participant description, participant selection, physical description of treatment setting, treatment fidelity, testing procedure description, or social validity. None of the studies established experimental control.

In summary, teaching a paragraph strategy had a large effect on the paragraph writing of students in Grades 8 and 9 (struggling and regular writers). Considerable caution must be exercised in interpreting this finding, as none of the studies established experimental control. Moreover, failure to adequately describe participants, selection procedures, and settings in a majority of studies narrows generalizations about whom and under what conditions this treatment is effective. It was unclear whether the treatment was delivered as intended in the majority of studies, nor was it clear that teachers or students valued this treatment.

### *Self-Monitoring*

Eight studies examined the effects of self-monitoring procedures (see Table 2). Self-monitoring procedures in these studies

included monitoring and graphing: the number of words and sentences written (Goddard, 1998), on-task behavior (Harris, Graham, Reid, McElroy, & Hamby, 1994; Moran, 2004; Rumsey & Ballard, 1985), or on-task behavior plus written productivity (Wolfe, 1997). Seven studies included a similar measure: productivity. Productivity included (a) total number of sentences (Goddard, 1998), (b) total number of words (Goddard, 1998; Harris et al., 1994; Jackson, 1994; Moran, 2004; Rumsey & Ballard, 1985; Wolfe, 1997), and (c) total number of written items completed (Shimabukuro, Prater, Jenkins, & Edelen-Smith, 1999).

There were 35 students in the seven self-monitoring studies (Grades 2, 3, 5–7) that assessed productivity (see Table 2). All of these students were struggling writers, and the majority of youngsters (57%; 15/35) were classified as having learning disabilities or ADHD. Most of the students were boys (80%; 28/35). Race/ethnicity was only reported in three studies, and location was provided in four of them (all but one of these studies were in suburban schools). Teachers delivered the treatment in the majority of the investigations (57%; 4/7). The effectiveness of self-monitoring was assessed through multiple-baseline and withdrawal designs.

Depending on the central tendency measure used, mean or median, self-monitoring was either ineffective or had a small impact on writing productivity (see Table 3). The median PND was 43%, whereas the mean PND was 51% (range = 93% to 23%).

On average, the self-monitoring studies met two thirds of the 11 quality indicators (see Table 5). Six quality indicators were met by just one half or less of the studies. These included participant description, participant selection, physical description of setting, treatment fidelity, description of testing procedures, and social validity. In addition, less than one half of the seven self-monitoring studies that assessed productivity established experimental control (see Table 2).

In summary, the effectiveness of self-monitoring was unclear, as the mean PND was in the small effect range, but the median PND indicated that the treatment was ineffective. Moreover, considerable caution must be exercised in interpreting any conclusions for this treatment, as experimental control was established in only 43% of studies. Failure to adequately describe participants, settings, and selection procedures in the majority of studies narrows generalizations about whom and under what conditions this treatment is effective. In addition, only one half of the studies established treatment fidelity, weakening the claim that the independent variable was responsible for changes in students' writing behaviors.

## Discussion

Writing is a critical skill in an advanced technological society. The future aspirations of students who do not master the writing process are at risk, as strong writing skills are needed to attend college and obtain more than menial employment (Graham & Perin, 2007b). An important ingredient in ensuring that students become skilled writers involves teachers' use of effective writing practices. Previous meta-analyses have examined true- and quasi-experimental writing intervention studies to identify such practices (Bangert-Drowns, 1993; Bangert-Drowns et al., 2004; Goldring et al., 2003; Graham, 2006a; Graham & Harris, 2003; Graham &

Olinghouse, in press; Graham & Perin, 2007a, 2007b; Hillocks, 1986). This meta-analysis extends these efforts to single subject design writing intervention studies, providing a broader base for making evidence-based recommendations for teaching writing.

## Caveats and Limitations

Before summarizing the primary findings from this review, it is important to explore the limitations of such an analysis. First, a meta-analysis, like the one conducted here, involves aggregating the findings from individual studies to draw a more general conclusion about a treatment. The value and breadth of a general conclusion depends on a variety of factors, such as who participates in the studies (grade and type of learner) and the quality of the investigations. For example, it would be inappropriate to draw a broad conclusion about a treatment for all students if the treatment was only tested with primary grade students. Consequently, our generalizations about the effectiveness of specific treatments are appropriately restricted to the grades and types of students tested. They are also constrained by study quality. Of course, more confidence can be placed in a conclusion drawn from this review if it is also supported by findings from other types of research (e.g., experimental and quasi-experimental research). Consequently, we also relate the findings from this review to prior reviews (e.g., Graham & Perin, 2007a, 2007b; Hillocks, 1986). In fact, we think that decisions concerning evidence-based teaching practices are most productive when they are based on all available evidence, including qualitative, correlational, experimental, and single subject research (Graham & Harris, in press).

Second, the effect size metric, PND, used in this study can only be calculated when data for each assessment point is available in the research report. Fortunately, we had only to eliminate two studies that did not provide the needed information (many more would have been eliminated if we had used the regression effect method). Nevertheless, it was not possible to compute PND for overall writing quality in most of the studies included in this review (this variable was often measured but not graphed). This variable has been the primary focus of previous meta-analyses of true- and quasi-experimental writing intervention research (e.g., Graham & Perin, 2007a; Hillocks, 1986). It is also important to note that PND and Cohen's *d* (the effect size of choice in the meta-analyses of group experimental studies) are not directly comparable.

Third, some instructional procedures have been the focus of more single subject design research than others. For example, strategy instruction for revising may be an effective procedure (see Appendix), but there are not enough single subject studies available to draw even a tentative conclusion about its impact. Moreover, there was only one treatment, strategy instruction for planning/drafting, that involved 10 or more single subject design tests of its effectiveness. A similar problem existed in the most current meta-analysis of true- and quasi-experimental design writing intervention studies (Graham & Perin, 2007a), as only four treatments (strategy instruction, word processing, processing writing approach, and grammar instruction) yielded 10 or more effect sizes. Less confidence can be placed in evidence-based recommendation based on a small number of studies. There is clearly a need for additional replication as well as the study of new treatments. Between this review and Graham and Perin's (2007a) meta-

analysis, only 213 investigations of writing interventions were located. It is obvious that the research base in writing is unacceptably thin. Simply put, federal agencies, such as the Institute of Educational Sciences and the National Institutes of Health, need to make writing a priority, making monies available for conducting more writing intervention research and preparing new researchers.

Fourth, one concern with meta-analysis involves comparability of outcome measures on which the effect sizes are based. We addressed this problem by only computing a summary PND (mean, median, and range) for a treatment when there were at least four or more studies that graphed a conceptually similar measure (i.e., productivity). It must be noted, however, that there were many instances where these conceptually similar measures were not exactly the same. For example, productivity typically involved number of words written but also included number of sentences. This introduces some unwanted noise into the machinery of meta-analysis.

### *What Instructional Practices Improve Students' Writing?*

We were able to calculate summary PNDs (mean, median, and range) for 10 writing treatments. For all but one treatment, the median and mean PND are all above the ineffective range (50% or below) established by Scruggs et al. (1986). The one exception was self-monitoring, where the mean PND was slightly above 50%, but the median was below this level. We do not offer a recommendation for this treatment, as its effectiveness is questionable and research quality in this area is generally poor.

In summarizing our findings, we included a recommendation, the median and mean PND for the treatment, grade range of students tested for each treatment, and the type of student to whom the recommendation best applied (typical students, struggling writers, or both). We did not analyze the data race/ethnicity, as these statistics were absent in almost one half of the studies. We also indicated when treatment findings need to be interpreted more cautiously due to poor study quality. The 10 recommendations were ordered according to two factors. Treatments that were based on the strongest research evidence were presented before treatments based on weaker evidence (this was determined by considering both the establishment of experimental control and the quality of studies). When the strength of the evidence was generally equivalent, then treatments with larger median PNDs were presented before ones with smaller PNDs. We privileged median over mean PND, as the median is less susceptible to the influence of outliers and does not necessitate the use of an equal interval scale (PND is based on percentage).

1. Teach students strategies for planning/drafting both narrative and expository text (treatment/posttreatment median PND for elements, productivity, and quality = 100%, 95%, and 99%, respectively; mean PND = 96%, 91%, and 99%, respectively). The effects of this treatment were not only maintained over time (3 weeks or longer; median PND = 100% for both elements and productivity; mean PND = 90% and 86%, respectively) but were generalized to untaught genres (median PND for elements = 86%; mean PND = 85%). Considerable confidence can be placed in the effectiveness of this treatment with struggling writers in Grades 2–8 and

typical writers in Grades 4–8. These findings also provided support for the SRSD model (Harris & Graham, 1996) of strategy instruction, as all of these studies used this model to teach the target strategies.

2. Directly teach grammar skills to struggling writers (median PND for grammar skills = 84%; mean PND = 83%). Confidence can be placed in the effectiveness of this treatment with students in Grades 2, 5, and 6.
3. Set clear and specific goals to increase students' writing productivity (median PND for productivity = 91%; mean PND = 79%). Confidence can be placed in the effectiveness of this treatment with struggling writers and typical students in Grades 2–5 and 8–12.
4. Teach students strategies for editing their compositions (median PND for reducing errors = 100%; mean PND = 84%). The confidence that can be placed in the effectiveness of this treatment with struggling and typical writers in Grade 4 and Grades 8–12 must be tempered somewhat due to concerns about the quality of the research.
5. Make it possible for students to use word processing as a primary tool for writing (median PND for productivity = 75%; mean PND = 70%). The confidence that can be placed in the effectiveness of this treatment with struggling writers in Grades 1, 4, and 5 must be tempered somewhat because of concerns about the quality of the research.
6. Reinforce students for their writing productivity (median PND for productivity = 100%; mean PND = 96%). The confidence that can be placed in the effectiveness of this treatment with struggling and typical writers in Grades 3–6 must be tempered somewhat because of concerns about the quality of the research.
7. Engage students in prewriting activities for gathering and organizing ideas in advance of writing (median PND for writing quality = 55%; mean PND = 52%). The confidence that can be placed in the effectiveness of this treatment with struggling writers in Grades 3–5, 8, and 12 must be tempered because of concerns about the lack of experimental control in the majority of studies.
8. Teach students how to form complex sentences (median PND for complete sentences produced = 83%; mean PND = 86%). The confidence that can be placed in the effectiveness of this treatment with struggling and typical writers in Grades 6–12 must be tempered somewhat because of concerns about the quality of the research and lack of experimental control.
9. Teach students strategies for writing different types of paragraphs (median PND for paragraph elements = 100%; mean PND = 97%). The confidence that can be placed in the effectiveness of this treatment with struggling and typical writers in Grades 8 and 9 must be

tempered considerably because of concerns about the quality of the research and lack of experimental control.

### *How the Findings From This Meta-Analysis Support, Extend, and Contradict Prior Findings*

Although it is not possible to compare directly the findings from this meta-analysis and previous ones examining true- and quasi-experimental writing intervention studies, the findings from this review support and extend findings from these previous analyses. Consistent with previous reviews involving both group experimental studies (Graham, 2006a; Graham & Harris, 2003; Graham & Perin, 2007a, 2007b) and single subject design investigations (Graham, 2006a; Graham & Harris, 2003), this review provided strong support for the effectiveness of teaching planning/drafting strategies to typical and struggling writers. It also provided further validation of the effectiveness of the SRSD model (Harris & Graham, 1996). Additional work needs to be done in this area, however, as such strategic instruction has mostly involved only stories and persuasive text, it has not covered all grade levels, and there is virtually no evidence on whether its effects are maintained past 6 months.

Consistent with previous reviews of experimental group studies (Bangert-Drowns, 1993; Goldring et al., 2003; Graham & Perin, 2007a, 2007b), word processing also had a positive impact on students' writing. This analysis extends these previous findings by demonstrating the effectiveness of word processing with struggling writers (this was not specifically examined in prior reviews). Likewise, we found that prewriting activities enhanced the quality of text produced by struggling writers. A previous meta-analysis of true- and quasi-experimental studies by Graham and Perin (2007a, 2007b) found a similar impact for more typical writers.

Replications and extensions between the findings from our review and previous meta-analyses involving group experimental studies were further found for goal setting and sentence construction. Graham and Perin (2007a, 2007b) indicated that establishing clear and specific writing goals improved the quality of text produced by typical and struggling writers. Our review of single subject design studies also supports the effectiveness of this treatment with typical and struggling writers but extends its impact to writing productivity. In addition, Hillocks (1986) as well as Graham and Perin (2007a, 2007b) reported that sentence combining was an effective practice for improving the quality of students' writing (only one of the studies reviewed involved struggling writers). We found that teaching sentence construction skills (including sentence combining) had a positive impact on the number of complete sentences produced by both typical and struggling writers (although most studies involved struggling writers).

Our review of single subject design writing intervention studies provided evidence on the effectiveness of several writing treatments that were not examined in prior reviews. This included reinforcing students' writing productivity, teaching strategies for editing text, teaching strategies for constructing paragraphs, and self-monitoring of writing productivity. With the exception of self-monitoring (which involved only struggling writers and produced questionable effects), these treatments were effective with typical and struggling writers. Noticeably missing from this and other reviews (e.g., Graham & Perin, 2007a, 2007b) were recommendations specifically on teaching strategies for revising content.

Unfortunately, there are very few single subject design studies (see Appendix) or experimental studies (see Graham & Perin, 2007a) that examined the effectiveness of such instruction. Clearly, additional research is needed in this area.

One area where our results were at odds with the finding of other reviews involved the teaching of grammar/usage. In their meta-analyses of true- and quasi-experimental studies, Hillocks (1986) and Graham and Perin (2007a, 2007b) reported that traditional grammar instruction did not enhance the quality of students' writing. In a narrative review of the research in this area, Andrews et al. (2006) also indicated that such instruction did not enhance students' grammar in text. In contrast, we found that grammar/usage instruction had a positive impact on the correct use of grammar in the text written by struggling writers. One explanation for this difference involves the type of writers studied. The reviews of group experimental studies focused almost exclusively on typical writers, whereas the participants in the single subject design studies were all weaker writers. It is also possible that the difference in findings was due to the methods used to teach grammar. In the single subject design studies, grammar/usage was primarily taught by the teacher modeling how to correctly apply the skill in writing, followed by students practicing applying the skill, with teacher assistance as needed. This was not typically done in the group experimental studies. In any event, additional research is needed to determine effective procedures for improving grammar in the writing of both typical and struggling writers.

### *Quality of Research*

This review provided some important insights into the strengths and weaknesses of current single subject design writing intervention research. When we looked at all studies together, we found that researchers consistently quantified their dependent variables, collected multiple baseline and intervention data points for writing, and adequately described their treatment. However, many researchers failed to adequately describe their participants, the processes used to select them, or the setting in which instruction took place, narrowing generalizations about to whom and under what conditions treatments are effective. In addition, evidence that a treatment was implemented as intended was provided in just 4 out of every 10 studies, raising uncertainty about treatment fidelity. It must be noted, however, that failure to collect such data, especially for older studies, does not mean that the independent variable was in fact compromised, as it has only become common to report treatment fidelity in the last 10 years or so (Graham & Perin, 2007a). Two other areas that are in need of some improvement involved adequately describing testing procedures (this did not occur in 1 out of every 3 studies) and collecting information on the social validity of a treatment (this did not occur in 4 out of every 10 studies).

Perhaps most importantly, many researchers failed to establish experimental control for one or more graphed variables in their study (this occurred 40% of the time for studies included in Table 2). There was also considerable variability across treatment categories in terms of the quality of studies and establishment of experimental control. This led us to clarify how much confidence could be placed in specific recommendations. Our analysis of the quality of individual studies indicated that there is considerable room for improvement in single subject design writing interven-

tion research, especially in terms of describing who participates and where instruction took place, documenting treatment fidelity, describing testing procedures, assessing social validity, and establishing experimental control. Researchers and those who review future research in this area (e.g., as journal reviewers and dissertation committee members) need to ensure that these problems are addressed.

### *Issues Involved in Implementing the Recommendations*

Implementing research-based treatments is a challenging task. Just because a treatment was effective in a research study does not guarantee that it will be effective in all other situations. There is rarely, if ever, a perfect match between the conditions under which the research was implemented and the conditions in which it is subsequently put to use by practitioners. Even when the match is good, the safest course of action is to monitor continually the effects of the treatment to gauge directly whether it is effective under the new conditions.

It is also important to note that we do not know what combination or how much of each of the recommended treatments in this review or other reviews (e.g., Graham & Perin, 2007a) is needed to maximize writing instruction. There is some preliminary evidence, however, that integrating some treatments can be beneficial (see Danoff, Harris, & Graham, 1993; Sadoski, Wilson, & Norton, 1997). Furthermore, the recommendations for teaching writing from this and other recent reviews (e.g., Graham & Perin, 2007a) are incomplete, as they do not address all aspects of writing (e.g., writing vocabulary, classroom-based assessment, parental participation, and use of new technologies, motivation).

A final issue in implementing evidence-based writing practices and recommendations revolves around the different organizational structures or formats for teaching writing that exist in schools. At the elementary level, regular classroom teachers, special education teachers, other specialists (e.g., reading specialists), and aides may all be involved in one or more aspects of writing instruction. At the secondary level, writing instruction may occur within the context of the language arts or English classroom, other content classrooms (such as history or biology), or with a learning specialist (such as a special education teacher). At either level, writing might be taught as a separate subject, in conjunction with content learning in some classes or subjects, or infused throughout the curriculum. The effectiveness of these various formats has neither been tested nor compared one to another (Graham & Perin, 2007a). Furthermore, it is not certain how well the evidence-based practices identified in this or other reviews would fare in these different formats. Before implementing one or more of these treatments identified in this review, careful analysis of the organizational structure or format within which it will be placed should be undertaken, with the aim of identifying factors that may facilitate or impede effectiveness.

### *Concluding Comments*

Meta-analysis provides a useful tool for drawing "important insight from what might otherwise be a confused and disparate literature" (Bangert-Drowns et al., 2004, p. 52). The writing intervention literature in general, and single subject design studies in this area, clearly fit this description, as they tested the effectiveness

of a wide range of interventions. We capitalized on the strengths of meta-analysis to conduct a comprehensive review of writing treatments assessed via single subject design. This was a productive strategy, as we were able to draw nine evidence-based recommendations for teaching writing.

# Primary Grade Writing Instruction: A National Survey

Laura Cutler  
University of Maryland

Steve Graham  
Vanderbilt University

A random sample of primary grade teachers ( $N = 178$ ; 97% female) from across the United States was surveyed about their classroom instructional practices in writing. Most of the participating teachers (72%) took an eclectic approach to writing instruction, combining elements from the 2 most common methods for teaching writing: process writing and skills instruction. Although 90% of the teachers reported using most of the writing instructional practices that were included in the survey, there was considerable variability between teachers in how often they used specific practices. The study provides support for the following 7 recommendations for reforming primary grade writing instruction: (a) increase amount of time students spend writing; (b) increase time spent writing expository text; (c) provide better balance between time spent writing, learning writing strategies, and teaching writing skills; (d) place more emphasis on fostering students' motivation for writing; (e) develop stronger connections for writing between home and school; (f) make computers a more integral part of the writing program; and (g) improve professional development for writing instruction in teacher education programs.

**Keywords:** writing, primary grades, instruction, composition, instructional practices

Reading and mathematics have received considerable attention in recent efforts to improve schooling in the United States. For example, the No Child Left Behind Act of 2001 focused considerable attention and effort on improving students' skills in each of these domains. However, the second of the traditional three *Rs*, writing, was not emphasized in the No Child Left Behind Act of 2001 and has been virtually nonexistent in the school reform efforts in this nation (despite the efforts of groups such as the National Commission on Writing working to change this situation; see <http://www.writingcommission.org>).

Why is writing the absent *R* in the school reform movement? One thing is for certain: It is not because students are developing the writing skills they need to be successful. Take for instance the findings from the most recent National Assessment of Educational Progress (NAEP; Persky, Daane, & Jen, 2003). The writing of two thirds or more of the students tested in Grades 4, 8, and 12 was below grade-level proficiency. The results from the previous NAEP report yielded similar findings (Greenwald, Persky, Ambell, & Mazzeo, 1999). Just as importantly, many youngsters leave high school lacking the writing skills needed for success in college or the world of work. College instructors estimate that 50% of high school graduates are not prepared for college-level writing demands (Achieve, Inc., 2005), whereas businesses in the United States spend \$3.1 billion annually for writing remediation (National Commission on Writing, 2004). In 2003, the National Com-

mission on Writing bluntly concluded that the writing of students "is not what it should be" (p. 7).

Another possible reason for why writing is not at the center of the school reform movement is that writing is not an important skill in the 21st century. This is also not the case. Youngsters who do not learn to write well are at a considerable disadvantage. At school, their grades are likely to suffer, especially in classes where written tests and reports are the primary means for assessing progress (Graham, 2006b). Weaker writers are also less likely than their more skilled classmates to use writing to support and extend learning in content classrooms. Recent meta-analyses have shown that writing can enhance content learning (Bangert-Drowns, Hurley, & Wilkinson, 2004; Graham & Perin, 2007c). Their chances of attending college are reduced, as writing is increasingly being used to evaluate applicants' qualifications. At work, writing is a gateway for employment and promotion, especially in salaried positions (see reports by the National Commission on Writing, 2004, 2005). Employees in business as well as government must be able to create clearly written documents, memorandum, technical reports, and electronic messages. Finally, participation in civic life and the community at large has increasingly required the ability to write, especially as the use of e-mail and text messaging has become so widespread.

The importance of writing and concerns about the writing competence of students led the National Commission on Writing, which was established by the College Board (representing more than 4,300 colleges and schools), to issue a report in 2003 indicating that writing needs to be placed "squarely in the center of the school agenda" (p. 3). This call to action also included several recommendations regarding writing instructional practices: increase amount of writing students do within and outside of school, assess students' progress in writing, use technology to advance the learning and teaching of writing, and better prepare teachers to teach writing.

One barrier to evaluating and implementing these suggestions and other recent recommendations for improving the teaching of writing (see *Writing Next*; Graham & Perin, 2007a, 2007c) is that researchers currently have little data on what writing instruction looks like in schools. They do not have a good sense of how much students write or what they write. They also do not know how much time is devoted to writing instruction; what writing skills, processes, or knowledge are taught to students; what methods are used to teach writing; how or even if technology is part of the writing program; or whether teachers assess students' writing progress. Without such information, it is difficult to determine what needs to be done. For instance, calls to increase the amount of time students write provide a reasonable part of the remedy, if students write infrequently. However, the potential value of this solution is less certain if students already write frequently.

In this study, we examined the writing instructional practices of primary grade teachers. Instead of concentrating on how writing was taught in a single school, district, or state, we focused instead on the teaching of writing across the nation. Consequently, we randomly sampled teachers from across the United States and asked them to complete a questionnaire about writing and writing instruction in their classroom. This approach to the study of classroom practices is based on the assumption that teachers are aware of the elements of their teaching and are able to relate this knowledge to questions about their teaching practices, just as other professionals can relate what they do when queried about their actions (Diaper, 1989). There is evidence that teachers are able to do this, as previous studies using survey methodology to examine teachers' literacy practices are corroborated by findings from observational research (see for instance Bridge & Hiebert, 1985; DeFord, 1985; Pressley, Rankin, & Yokoi, 1996).

We decided to focus on primary grade writing instruction for several reasons. One, it is especially important that students get off to a good start in writing. There is a growing consensus that waiting until later grades to address literacy problems that have their origin at the primary level is not particularly successful (Slavin, Madden, & Karweit, 1989). Thus, reform efforts in writing are likely to be hampered if the primary grades are not included (Graham & Perin, 2007b). Two, while NAEP has collected some limited data on writing practices nationwide, it does not solicit information on the teaching of writing in the primary grade (Applebee & Langer, 2006). Insufficient data about writing practices at this level increase the probability of recommending solutions that do not fit the problem.

There is surprisingly little data on the instructional writing practices of primary grade teachers. Most of the available information examines the writing programs of exceptional teachers or schools (see Pressley, Gaskins, Solic, & Collins, 2006; Pressley, Mohan, Bogaert, & Fingeret, 2005; Pressley et al., 1996; Pressley, Raphael, Gallagher, & DiBella, 2004; Rankin-Erickson, & Pressley, 2000; Wharton-McDonald, Pressley, & Hampston, 1998; Wray, Medwell, Fox, & Poulson, 2000). Although the practices of more typical teachers have been studied, much of this research is dated (e.g., Bridge & Hiebert, 1985; Christenson, Thurlow, Yseldyke, & McVicar, 1989; Fisher & Hiebert, 1990). We located only three studies conducted during the 1990s and 2000s that involved more typical teachers. It is unlikely, however, that the findings from the first two studies reviewed below provide a representative picture of writing instruction nationwide. Stahl,

Pagnucco, and Suttles (1996) examined three classes in one school where the principal made it clear that he ran the school and he expected his teachers to emphasize writing skills instruction. They also examined three classes in a new school, where the principal hand picked teachers who followed a whole language philosophy to literacy instruction. These schools represent each end of the writing instruction continuum ranging from explicit teaching to natural learning approaches (Graham, 2000). In the second study, Bridge, Compton-Hall, and Cantrell (1997) examined how writing instruction in a school district in Kentucky was influenced by statewide legislation on literacy instruction. While some aspects of this school reform effort mirrored what occurred in other states, only the practices of a single school district were studied, limiting the overall generalizability of the findings.

A third study, however, did provide representative information on contemporary writing instruction in the primary grades. Graham, Harris, Fink-Chorzempa, and MacArthur (2003) sent a survey questionnaire to a random sample of primary grade teachers from throughout the United States. Seventy percent of teachers completed the survey, and responders and nonresponders were similar in terms of gender, grade, type of school (public versus private), school location (urban, suburban, and rural), school size, computers per pupil, and expenditures per pupil. Although the primary purpose of this study was to identify the types of instructional adaptations that teachers made for struggling writers, it also provided information on specific aspects of their writing program.

The teachers in the Graham et al. (2003) investigation indicated that their students spent slightly more than 35 min writing each day. They further indicated that they spent a little more than 1 hr a day teaching writing, with most of this time being devoted to teaching mechanics, grammar, and usage. These basic skills were typically taught several times a week or more, whereas writing processes (planning and revising) were most often taught weekly to several times a week. Most teachers also conducted minilessons on writing, retaught skills, modeled writing processes, and conferred with students about their writing at least weekly or more often. The use of invented spellings, student choice in selecting writing topics, and allowing children to work at their own pace on writing assignments were relatively common practices, as was students helping each other and sharing their writing with peers. Less common was student use of computers during the writing period, with this occurring monthly or less in 60% of classrooms. It must be noted that there was considerable variability in teachers' responses to many of the items on the questionnaires, especially ones that asked them to estimate how much actual time was devoted to teaching or student writing.

Although the Graham et al. (2003) study provided needed information on contemporary instructional practices in writing, it was incomplete. Teachers were only asked how frequently they engaged in activities and procedures that could easily be adapted. The current study extends the Graham et al. (2003) investigation by examining a much broader range of instructional practices and activities, and it examines whether teachers' reported application of these procedures is related to grade level. To select these writing procedures, we first examined studies from 1980 to the present where primary grade teachers were asked to report their writing practices or researchers observed how they taught writing (this included studies of exceptional teachers and schools). We supplemented this analysis by examining current books on how to teach

writing to young children to locate other activities and practices not queried or observed in the studies analyzed. This does not mean that we surveyed every possible writing procedure, but it does provide some assurance that we asked teachers about practices that have been applied in the past and ones that are considered important by experts on the teaching of writing.

The activities and practices included in our survey instrument reflect the most common theoretical views of writing and writing instruction. This included cognitive/motivational (e.g., Hayes, 1996) and sociocultural models of writing (e.g., Schultz and Fecho, 2000), as well as instructional models that emphasize the explicit teaching of skills and strategies (see Graham, 2006b) and those that emphasize process and communication (see Vaca & Rasinski, 1992). We were particularly interested in determining whether primary grade teachers' writing programs reflected a process approach to writing instruction (emphasis is placed on the act of composing and instruction is mostly provided through informal means when the need arises), a skills-based approach (emphasis placed on systematic instruction of basic writing skills), or a combination of the two approaches. We hypothesized that teachers would take an eclectic approach to writing instruction, applying instructional procedures that cut across these two common approaches. We based this prediction on a study by Graham, Harris, Fink-Chorzempa, and MacArthur (2002), who found that most primary grade teachers had multifaceted beliefs about writing instruction, embracing both systematic skill instruction and informal learning methods, while emphasizing that the process of writing is more important than the product.

A second purpose of this study was to examine typical writing practices in order to draw recommendations for improving writing instruction in the primary grades. This included drawing new recommendations from the description of classroom practices generated by the teachers, as well as examining the value of the following four existing recommendations made by the National Commission on Writing (2003), indicating in parentheses where we placed our emphasis: (a) students should write more (examining how much students write text that is paragraph length or longer), (b) technology needs to be a more integral part of writing instruction (examining computer use in the writing program), (c) students progress in writing needs to be monitored (examining monitoring of writing progress in the classroom), and (d) teachers need to be better prepared to teach writing (examining teachers' perceptions of the quality of their preservice preparation to teach writing).

## Method

### *Sampling Procedures*

A random sampling procedure, stratified by grade level, was used to identify 294 first- through third-grade teachers from the population of primary grade teachers in the United States. The names were selected from a comprehensive list of 560,320 primary grade teachers in more than 72,000 public and private schools compiled by Market Data Retrieval (MDR). At each grade level, 98 teachers were randomly sampled from all public and private school teachers in the MDR data base (no other variables, such as geographic region, were used as part of the sampling scheme). We decided to use the MDR database, as this was used in the previous

national survey conducted by Graham et al. (2003), making the findings from the two studies more comparable. In addition, MDR provides information (grade, type of school, location, size of school, and school expenditure per pupil for commercial materials) for each person sampled. This allowed us to determine whether responders and nonresponders differed on several variables.

A sample size of 294 teachers (with 174 teachers completing the survey) is adequate for a population of 560,320 primary grade teachers under the following conditions (cf. Dillman, 2000): (a) a  $\pm 5\%$  sampling error is considered tolerable, (b) expected variation in teacher responses is equal to .125/.875, (c) the statistical confidence level is set at 95%, and (d) a return rate of 60% is obtained (this is a conservative estimate, as we obtained a return rate of 70% in Graham et al., 2003). Expected variation in teacher response rate refers to proportion of the population expected to choose a specific response to a question. The most common item in this survey (41 items) asked teachers to respond to an 8-point Likert-type scale. As a result, we used these items to determine expected variation in teacher response rate when determining needed sample size. Since we did not know what proportion of the population would be expected to choose each of the 8 points, we assumed an equal likelihood for selecting a point (yielding the .125/.875 split).

### *Survey Instrument*

Teachers were asked to complete a questionnaire that provided information about themselves, the composition of their classrooms, their attitudes and perceptions about writing and writing instruction, and their writing practices. The survey can be obtained by contacting Steve Graham.

The first section of the survey asked teachers to provide descriptive information on their gender, ethnicity, educational level, years spent teaching, and current grade level, as well as the class size and characteristics of their students (ethnicity, writing abilities, special needs, and socioeconomic status as determined by free and reduced lunch). This section also included a question asking teachers to rate (i.e., *exceptional*, *very good*, *adequate*, *poor*, *inadequate*) the quality of preparation to teach writing they received in their teacher certification program.

The second section included a series of four questions (using a 6-point Likert-type scale, with anchors ranging from *strongly agree* to *strongly disagree*) assessing teachers' attitudes towards writing ("I like to write") and teaching this skill, as well as their perceptions of their effectiveness to manage the writing classroom and teach writing.

The third section asked teachers to specify how much time their students spend writing each week and how much time they spend teaching specific skills and processes (i.e., spelling, handwriting, grammar, planning, and revising). Teachers were also asked to estimate what percentage of their instructional time was devoted to whole group, small group, and individualized instruction. They were further asked if they used a commercial program to teach any aspect of writing (and to identify the program if they did) and to identify the description that best described their approach to teaching writing: process writing, traditional skills instruction, a combination of the two, or some other approach (which the respondent was asked to describe). A final question asked them to indicate which writing activities students would work on during the academic year. This included a list of 20 options (ranging from

worksheets to writing to inform). Teachers were encouraged to identify any additional writing activities their students would complete that were not directly queried on the survey.

The fourth section included 41 Likert-type items. Each item focused on a specific activity or instructional procedure, and teachers were asked to indicate how often the practice was applied using an 8-point scale. The scale, developed by Pressley et al. (1996), included the following markers: 1 = *never*, 2 = *several times a year*, 3 = *monthly*, 4 = *several times a month*, 5 = *weekly*, 6 = *several times a week*, 7 = *daily*, and 8 = *several times a day*. The only exception involved three items ("invented spellings," "select own writing assignments," and "work at their own pace") where the 8-point scale ranged from *never* to *half the time to always*. The higher the score, the more often an activity or procedure occurred.

Eleven of the items asked teachers to indicate how often teachers, students, or both engaged in specific activities that supported the development of students' writing products (coefficient alpha = .78). These items focused on teacher/student conferences, student/student conferences, advanced planning, graphic organizers, revising, peers helping each other, writing at own pace, invented spellings, writing prompts, dictation, and computers for writing.

Six items examined how frequently teachers directly taught the following basic writing skills (coefficient alpha = .84): handwriting, spelling, capitalization, punctuation, grammar, and sentence construction. Another four items assessed how frequently writing processes were directly taught (coefficient alpha = .85), including modeling of writing strategies as well as teaching text organization, planning strategies, and revising strategies. Three items assessed more general instructional procedures (coefficient alpha = .62), including minilessons, reteaching, and setting multiple goals for writing lessons.

Six items addressed motivational activities and procedures (coefficient alpha = .70), including student selection of writing topics, sharing writing with peers, publishing, and working independently at writing centers, as well as teachers modeling their love of writing and sharing their writing with students. Four items assessed the use of the following assessment practices (coefficient alpha = .75): rubrics, writing portfolios, teacher monitoring of students' writing progress, and students' self-monitoring monitoring. Another four items assessed strategies used by teachers to extend writing to the home environment (coefficient alpha = .81): writing homework, writing at home with parental help, parents serving as an audience for child's writing, and teacher/parent communication. Finally, three items asked how often writing extended or interacted with other areas of the curriculum (coefficient alpha = .83): using writing to support reading, reading to support writing, and writing in other content areas.

For Sections 3 and 4 of the survey assessing teachers' writing practices, a pool of possible items were developed by first examining studies from 1980 to present where primary grade teachers were asked to report their writing practices or researchers observed how they taught writing (i.e., Bridge et al., 1997; Bridge & Hiebert, 1985; Christenson et al., 1989; Fisher & Hiebert, 1990; Graham et al., 2003; Pressley et al., 1996; Rankin-Erickson & Pressley, 2000; Stahl et al., 1996; Wharton-McDonald et al., 1998; Wray et al., 2000). A table containing each practice and activity observed or assessed was created, indicating which studies each assessed each procedure. Next, we examined current books on

teaching writing to young children (i.e., Culham, 1995; Duke & Bennett-Armistead, 2003; Gillet & Beverly, 2001; Mariconda, 2001; Nelson, Bahr, & Van Meter, 2004; Schaefer, 2001) and added recommended activities and practices to the table that had not been examined by researchers. With a few exceptions, we developed items for each of the practices and activities identified. We did not, for example, ask teachers if their students engaged in authentic writing (from Wharton et al., 1998) or scaffolding (from Pressley et al., 1996), as this term is too vague to be understood by respondents.

The instrument was field tested prior to its use in this study. Four primary grade teachers provided feedback on an initial version of the scale in terms of the clarity of each item. Their feedback resulted in changes to the wording of individual items, as well as the addition of the anchor point *several times a month* to the Likert-scale that ranged from *never* to *several times a day*.

We have collected some limited data showing that teachers' responses about their instructional practices are consistent with observations of their practices during writing period. In Lane et al. (2008), we asked 14 second-grade teachers to complete the 41 eight-point Likert-type items described above. We then conducted two observations of their writing instructional practices. With a few exceptions (i.e., we saw students plan and revise less frequently than teachers reported in the survey), the observations confirmed that the teachers applied the practices they reported using frequently in their classroom.

Furthermore, Olinghouse (2008) asked 13 second- and fourth-grade teachers to complete the items that asked teachers to specify exactly how much time students write and how much time the teachers spend teaching skills and processes (e.g., spelling, revising, etc.). They then observed each teacher's classroom on one occasion to determine whether reported time and observed time were similar. The reported and observed times were not statistically different.

## Procedure

A cover letter, the survey instrument, and a stamped return envelope were mailed to each teacher during the month of January. The cover letter indicated that we were conducting a survey to gather information on the teaching of writing at the primary grade level. Teachers were asked to return materials in the next 2 weeks if possible. To encourage completion and return of the survey, we included a \$2 bill in the package as a "thank you."

## Results

### Analyses

We first present information on the participating teachers. This includes comparing responders and nonresponders on the five variables (e.g., grade, type of school, etc.) provided by MDR. Next, using data from the survey, we describe the teachers and their students. This is followed by data about teachers' perceptions of their preparation to teach writing, their effectiveness as a writing teacher, and their attitudes toward writing and writing instruction. Finally, we examine the participants' reported teaching practices.

All together, the survey included 46 Likert-type items (5 assessed participants' preparation to teach writing and their and

attitude toward writing and writing instruction, whereas 41 items examined how often teachers, students, or both engaged in specific instructional activities and practices). Six items also asked teachers to indicate how much time during a typical week was devoted to specific activities (e.g., student writing, teaching handwriting, etc.), and 3 items asked teacher to indicate what percentage of their instructional time involved specific instructional arrangements (whole group, small group, and individualized). For all 54 of these items, we present the mean, standard deviation, and confidence interval (CI). We also examine whether there was a statistically significant relationship between grade level and teachers' responses using analysis of variance. When a statistically significant difference for grade was obtained, we used the least significant difference test to conduct post hoc analyses.

There were 20 items that asked teachers to indicate if their students would engage in specific writing activities during the year, 1 item that asked teachers to indicate their approach to writing instruction (e.g., process approach, skills approach, etc.), and 1 item that asked if materials were used to teach writing. Sampling error for these items was  $\pm 7.3\%$ . Chi-square analysis was used to determine whether there was a statistically significant difference by grade for each of these categorical variables. When a statistically significant chi-square was obtained, it was followed by a series of chi-squares comparing one grade to another.

In order to control for Type I errors, we set the critical alpha value using Bonferroni correction ( $\alpha = .05/68$ ) and rejected the null hypothesis if the  $p$  value was less than .00074. Using these criteria, there were few differences between teachers at different grade levels. Thus, the data presented in tables is for all teachers and grade level effects are addressed in text only if a statistically significant difference was obtained.

It is important to note that the responses for 30% of the items analyzed via analysis of variance did not meet the assumptions of homogeneity of variance due to skewness or kurtosis, with levels of one or more of these indices exceeding the range of  $\pm 1.96$  Fisher coefficient. For any variable where this was the case, we also ran the analysis using a nonparametric procedure—the Kruskal-Wallis procedure. In all cases, the results of parametric and nonparametric procedures were identical. Thus, we only report the parametric results in this article.

### *Participating Teachers and Their Students*

Of the 294 randomly selected primary grade teachers, 61% ( $n = 178$ ) agreed to participate in the study. Demographic information for the 178 responders as well as the 116 nonresponders is presented in Table 1. Chi-square analyses revealed no statistically significant differences between responders and nonresponders in terms of type of school (public vs. private), grade, or location of the school ( $p = .21, .75, .07$ , respectively). Analyses of variance further indicated that there were no statistically significant differences between responders and nonresponders in terms of school size or annual expenditures for materials per pupil ( $p = .29$  and  $.14$ , respectively). Thus, responders did not differ from nonresponders on these five demographic variables, providing evidence that the responders were representative of the sample as a whole.

Similar to previous surveys with primary grade teachers (Graham et al., 2003), almost all of the teachers were women (97%). For the most part, they were evenly distributed across the three

Table 1  
*Characteristics of Responders and Nonresponders*

Variable	Responders		Nonresponders	
	<i>n</i>	%	<i>n</i>	%
Type of school				
Public	158	89	107	92
Private	20	11	9	8
Grade				
First	58	33	42	36
Second	57	32	41	35
Third	63	35	33	28
Location				
Urban	39	22	33	29
Suburban	69	39	53	46
Rural	67	38	29	25
Size of school				
<i>M</i>	386.56		420.14	
<i>SD</i>	241.75		243.89	
Expenditures per pupil				
<i>M</i>	150.48		137.94	
<i>SD</i>	65.79		64.95	

grades. Two out of every 10 teachers were located in urban schools, with the remaining teachers split almost equally between suburban and rural locations. There was considerable variability in the size of the schools that employed the participating teachers.

As a group, the teachers had taught for 17 years ( $SD = 10$  years). They were overwhelmingly White (91%), with 4% of the teachers identifying themselves as Black, 2% as Hispanic, and 2% as other. Seventeen percent of the teachers had completed a master's degree plus additional coursework, 24% had completed a master's degree, 42% had completed a bachelor's degree plus additional coursework, and 16% had completed a bachelor's degree. Almost all of the teachers (92%) had attended a teacher certification program.

The average size of the participating teachers' class was 19.96 students ( $SD = 5.14$ ), with approximately 31% of their students qualifying for free or reduced-cost lunch. One tenth of their students were receiving special-education services, and the teachers indicated that 15% of their students were above average writers, 67% were average, and 21% were below average. In addition, 75% of the teachers' students were White, 11% were Hispanic, 10% were Black, 2% were Asian, and 2% were other.

### *Preparation to Teach Writing, Perceptions of Effectiveness, and Attitudes Toward Writing and Writing Instruction*

Of the 92% of teachers who had received certification through a teacher education program, 28% indicated that their preparation to teach writing was either very good or outstanding, 42% indicated that their preparation was adequate, and 28% indicated that it was poor or inadequate (sampling error =  $\pm 5.8\%$  for this item). Interestingly, the teachers' evaluation of their preparation to teach writing was not significantly related to how long they had taught ( $p = .06$ ). As can be seen in Table 2, teachers moderately agreed that they were effective writing teachers and managed their writing class effectively. They also moderately agreed that they liked to write and teach writing.

Table 2  
*Primary Grade Teachers' Perceptions of Their Effectiveness in Teaching Writing and Their Attitudes About Writing*

Survey question	n	M (SD)	CI
I like to teach writing.	177	5.0 (1.2)	4.8–5.1
I effectively manage my classroom during writing instruction.	177	5.1 (0.94)	4.9–5.2
I like to write.	177	4.7 (1.2)	4.6–4.9
I am effective at teaching writing.	175	4.8 (0.97)	4.7–4.9

Note. Scores range from 1 to 6, with higher scores indicating greater agreement. CI = 95% confidence interval.

Teaching Practices

*Approach to writing instruction and use of commercial materials.* When teachers were asked which best described their approach to writing instruction, 72% indicated that they used a process approach combined with a traditional skills approach, 20% a process approach, and 6% a traditional skills approach. For the 4 teachers who responded “other” approach, two of them indicated that they used the 6 + 1 trait method (Spandel, 2005), another provided a detailed description of their program (it included both process and skill instruction), and the fourth teacher referred to an approach that we were unable to identify.

For the most part, writing instruction in the primary grades was a home grown product: 65% of teachers reported that they did not use a commercial program to teach writing, handwriting, spelling, or any other aspect of writing (sampling error = ±7.3%). The other 35% of the teachers listed 137 different programs they used. The most common programs (45%) were designed to teach either handwriting or spelling. The next most common programs listed (36%) were basal language arts programs. The remaining programs ranged from 6 + 1 traits to writers’ workshop to skills-based writing programs.

*Organizational structure.* Teachers indicated they spend 56% (SD = 27%; CI = 52%–60%) of their instructional time with whole groups. Twenty-three percent (SD = 20%; CI = 20%–26%) of instructional time was devoted to small group instruction, with 24% (SD = 20%; CI = 21%– 27%) involving individualized assistance. There was considerable variability in how teachers organized their class for writing instruction (see standard deviations above).

*Writing activities.* Table 3 provides information on 20 writing activities and the percentage of teachers who reported that their students would complete each activity during the school year. At least 50% or more of the teachers have students work on 12 or more different writing assignments during the year, with the most common assignments involving story writing, drawing a picture and writing something to go with it, writing letters, journal writing, completing worksheets, composing a personal narratives, responding in writing to material read, and writing poems.

For five of the writing activities, there was a statistically significant difference by grade: writing summaries,  $\chi^2(2, N = 161) = 48.12, p < .00074$ ; writing to inform,  $\chi^2(2, N = 161) = 27.61, p < .00074$ ; writing to persuade,  $\chi^2(2, N = 161) = 36.28, p < .00074$ ; alphabet books,  $\chi^2(2, N = 161) = 17.44, p < .00074$ ; and biographies,  $\chi^2(2, N = 161) = 18.38, p < .00074$ ). For writing in

response to material read, follow-up analyses revealed that students in Grade 3 (93%) participated in this activity more than students in Grade 2 (72%; coefficient phi = .36) and Grade 1 (74%; coefficient phi = .28). Likewise, students in Grade 3 (97%) were more likely to write summaries than students in Grade 2 (60%; coefficient phi = .45) or Grade 1 (34%; coefficient phi = .66). Furthermore, Grade 2 students were more likely to write summaries than Grade 1 students (coefficient phi = .26). Similar results were obtained for writing to inform, as Grade 3 students (85%) were more likely to do this activity than were Grade 2 (56%; coefficient phi = .31) or Grade 1 students (36%; coefficient phi = .50). Similarly, students in Grade 3 (67%) were more likely to write to persuade than were students in Grade 2 (30%; coefficient phi = .37) or Grade 1 (13%; coefficient phi = .55). In contrast, students in Grade 1 (55%) were more likely to compose an alphabet book than students in Grade 3 (17%; coefficient phi = .39). Finally, Grade 3 students (50%) were more likely to write biographies than were Grade 2 (26%; coefficient phi = .25) or Grade 1 students (13%; coefficient phi = .39).

In addition to indicating whether their students completed the 20 listed writing activities, teachers were asked to identify any additional writing activities that their students completed over the course of the school year. Twenty-three percent (n = 40) of the teachers listed additional activities. The additional writing activities ordered from most frequent to least frequent were content area writing in math and science (21.7%), invitations and thank you notes (10.8%), descriptive writing (10.8%), newspaper articles (8.7%), instructions (8.7%), compare and contrast writing (8.7%), research reports (4.1%), writing to a prompt (4.7%), cause and effect writing (3.1%), note taking (3.1%), reflection/opinion writing (3.1%), and writing sentences (3.1%). In addition, 13 writing activities were listed only one time by respondents (i.e., phone

Table 3  
*Types of Writing Activities Students Do During the Academic Year by Frequency*

Writing activity	% of teachers who responded yes
Stories	96.1
Drawing a picture and writing something to go with it	94.9
Writing letters to another person	88.8
Journal writing	86.5
Completing worksheets	86.0
Personal narratives	79.8
Writing in response to material read	78.1
Poems	75.3
Writing summaries	65.7
Lists	65.2
Book reports	62.4
Writing to inform	59.0
Books	48.3
Copying text	42.7
Writing to persuade	36.0
Alphabet books	33.7
Autobiographies	29.2
Biographies	28.1
Comic strips	16.9
Plays	15.7

Note. Sampling error ±7.3%

messages, riddles, alliteration, dialogue, story problems, onomatopoeia, prayers, recipes, personal recounts, labels, cartoons, graphic organizers, and e-mailing letters to pen pals in another state).

We further asked teachers to indicate how many minutes each week their students spend writing text that was paragraph length or longer. This included planning, drafting, revising, and editing text. There was considerable variability in amount of time reported, ranging from 0 min to 380 min ( $SD = 70.8$  min;  $CI = \pm 6.5$  min). As a result, we report the median response instead of the mean. The median amount of time students composed was 105 min per week (i.e., 21 min per day).

*Practices that support students' writing.* Table 4 presents means, standard deviations, 95% confidence intervals, and percentage of teachers who checked each anchor point for 38 of the 41 Likert-type items (8-point scale, ranging from 0 [*never*] to 7 [*several times a day*]) that assessed the use of specific writing instructional practices. For each category of items (i.e., support students' writing, teach basic writing skills, teach writing processes and strategies, etc.), items are arranged from most to least frequently occurring. Means, standard deviations, and 95% confidence intervals for the other three Likert-type items are presented in text. Although these items also employed an

Note. CI = 95% confidence interval.

8-point scale, the scale ranged from *never* (score of 0) to *always* (score of 8).

Two of the practices for supporting students' writing were assessed via the 8-point scale that ranged from *never* to *always*. One of these practices, encouraging students to use invented spellings, was applied frequently ( $M = 5.3$ ;  $SD = 1.9$ ;  $CI = 4.9-5.5$ ). Eighty four percent of teachers reported that they encouraged the use of invented spellings at least half of the time or more, with 37% indicating they always encouraged the use of this practice. Although students' selection of their own writing topics was less common ( $M = 3.6$ ;  $SD = 1.4$ ;  $CI = 3.4-3.8$ ), 63% of teachers reported applying this practice at least half of the time (only 3% always allowed students to chose their own writing topics).

As can be seen in Table 4, the majority of teachers reported that they used the following procedures to support students' writing at least weekly or more often: graphic organizers, writing prompts, teacher conferences with students about their writing, and planning in advance of writing. Several times a month or more often, the majority of teachers indicated they had students revise their written products. There was considerable variability in how often students helped each other with their writing or conferenced with their peers about what they wrote. Depending upon the teacher, these practices typically occurred somewhere between several times a month and daily. Much less frequently applied was the use of computers or dictation to support students' writing. Forty two percent and 56% of teachers, respectively, reported that they never used these practices. Only about one third of the participating teachers used computers or dictation at least once a month or more often.

There was a statistically significant grade-level difference for one of the writing support practices: using graphic organizers,  $F(2, 157) = 14.75$ ,  $MSE = 45.65$ ,  $p < .00076$ . Follow-up analyses revealed that Grade 3 teachers reported using graphic organizers more often than Grade 1 teachers ( $p < .001$ ; effect size [ES] = .90; Grade 1:  $M = 3.50$ ,  $SD = 1.6$ ; Grade 3:  $M = 5.2$ ,  $SD = 1.8$ ).

**Teaching basic writing skills.** Teachers reported that they frequently taught basic writing skills (see Table 4). Spelling, grammar, capitalization, and punctuation skills were taught by a majority of the teachers daily, with at least three quarters of them teaching these skills at least several times a week. The majority of teachers also reported teaching handwriting and sentence construction skills several times a week to daily, with three quarters of them teaching these skills at least weekly or more often. It is interesting to note that it was extremely rare for a teacher to report that these skills were never taught.

For one of the basic writing skills, handwriting, there was a statistically significant grade level difference,  $F(2, 155) = 9.78$ ,  $MSE = 24.05$ ,  $p < .00076$ . Post hoc analysis revealed that Grade 1 ( $p < .001$ ; ES = .76) and Grade 3 teachers ( $p < .001$ ; ES = .66) reported teaching handwriting more often than Grade 2 teachers (Grade 1:  $M = 5.0$ ,  $SD = 1.6$ ; Grade 2:  $M = 3.7$ ,  $SD = 1.8$ ; Grade 3:  $M = 4.8$ ,  $SD = 1.2$ ).

When we asked teachers to specify how much time a week they spent teaching spelling, grammar/usage, and handwriting, the patterns were similar. The typical teacher reported spending 74 min a week teaching spelling ( $SD = 61.6$ ;  $CI = 65.1-83.7$ ;  $Mdn = 60.0$ ) and 80 min a week teaching grammar/usage ( $SD = 76.7$ ;  $CI = 68.4-91.5$ ;  $Mdn = 60.0$ ), but only 46 min a week teaching handwriting ( $SD = 37.2$ ;  $CI = 40.8-52.1$ ;  $Mdn = 30.0$ ). Again,

virtually all of the teachers devoted at least some time each week to teaching these skills.

**Teaching writing processes and strategies.** The majority of teachers reported modeling how to apply writing strategies as well as teaching students about text organization and planning strategies at least once a week (see Table 4), with such instruction most commonly occurring once a week to several times a week. Revising strategies were taught by most teachers at least several times a month, with this mostly occurring on a weekly or greater basis. Only 1 in 50 teachers reported that they never taught writing strategies.

Consistent with these findings are the amount of time teachers indicated that they spent teaching planning and revising strategies each week (we report means and medians due to the large standard deviations). The typical teacher reported spending 38 min a week teaching planning strategies ( $SD = 28.3$ ;  $CI = 32.9-43.9$ ;  $Mdn = 30.0$ ) and 33 min a week teaching revising strategies ( $SD = 35.0$ ;  $CI = 28.3-37.8$ ;  $Mdn = 30.0$ ).

**Instructional procedures for teaching skills and strategies.** The majority of teachers reported that they conducted minilessons several times a week or more to teach needed skills and writing processes (see Table 4), with 80% of teachers doing this at least weekly. The reteaching of skills and strategies previously taught, however, occurred less frequently, as the majority of teachers reported doing this somewhere between several times a month to several times a week. There was considerable variability in how often teachers reported designing writing instruction with multiple goals, but the majority of teachers did this at least weekly.

**Motivational techniques.** Over 80% of the teachers reported that their students were allowed to work at their own pace on writing assignments at least half of the time or more ( $M = 4.8$ ;  $SD = 1.6$ ;  $CI = 4.5-5.0$ ), with approximately 1 in 5 teachers indicating that this always occurred. As can be seen in Table 4, a majority of the teachers indicated that students shared their writing with their peers at least weekly (no teacher responded "never" to this question). Although there was considerable variability in how often teachers modeled their enjoyment or love of writing, the majority of teachers also did this at least weekly. It was less common for teachers to share their own writing with students, have children publish their work, or work independently at a writing center. The majority of teachers did this monthly or less, and a sizable proportion of teachers did not use writing centers (35%) or share their writing with students (19%).

**Assessing writing.** The majority of teachers reported that they monitored their students' writing to make decisions about writing instruction at least weekly or more often (see Table 4). They also encouraged their students to monitor their own writing progress at a similar rate. In contrast, a sizable proportion of teachers reported that they did not have their students build writing portfolios (32%) or use rubrics to assess their writing (32%). When either of these practices were applied, they were more likely to occur several times a year to monthly.

There was a statistically significant grade-level difference in how often teachers reported monitoring students' writing progress,  $F(2, 154) = 9.84$ ,  $MSE = 22.10$ ,  $p < .00076$ .

Post hoc analyses revealed that Grade 1 ( $p < .001$ ; ES = .75) and Grade 3 teachers ( $p < .001$ ; ES = .68) reported that they were more likely to monitor the writing of their students than Grade 2

teachers (Grade 1:  $M = 4.5$ ,  $SD = 1.6$ ; Grade 2:  $M = 3.3$ ,  $SD = 1.6$ ; Grade 3:  $M = 4.4$ ,  $SD = 1.2$ ).

*Extending writing to the home.* Among the least common practices were teachers' reported efforts to extend writing to the home (see Table 4). For example, the two most common responses to assigning writing homework were never (23%) and several times a year (26%). Similar patterns were evident for asking parents to listen to something the child wrote at school (never = 29%; several times a year = 36%) or help their child write at home (never = 34%; several times a year = 28%). While all but a small percentage (7%) of teachers communicated with parents about their child's writing progress, slightly more than 2 out of every 3 teachers did this only several times a year.

*Connecting writing to reading and other content areas.* Although there was considerable variability in how often teachers reported using writing to support reading or students using writing in other content areas, these practices occurred at least weekly or more often with the majority of the teachers (see Table 4). It was less common for teachers to report using reading to support writing, with the largest proportion of teachers applying this practice either several times a year or several times a month.

There were grade-level differences in how frequently teachers reported using writing in other content areas,  $F(2, 157) = 7.08$ ,  $MSE = 18.56$ ,  $p = .000761$ . Grade 3 teachers were more likely to have their students write across the curriculum than Grade 2 teachers ( $p < .001$ ;  $ES = .69$ ; Grade 2:  $M = 3.0$ ,  $SD = 1.8$ ; Grade 3:  $M = 4.2$ ,  $SD = 1.4$ ).

## Discussion

By fourth grade, 2 out of every 3 children in the United States do not write well enough to meet classroom demands (Persky et al., 2003). This places these children at risk because writing is essential to educational and occupational success (National Commission on Writing, 2004, 2005). Concerns about students' writing development has led to calls to make writing a central element in the school reform movement, stressing that students need to write more, technology needs to be a more integral part of writing instruction, students' progress in writing needs to be monitored, and teachers need to be better prepared to teach writing (National Commission on Writing, 2003). While the need for better writing instruction cuts across all grade levels, we think that it is especially important to make improvements when children are first learning to write. It is difficult in later grades to overcome literacy problems that have their origin in the primary grades (Slavin et al., 1989). The development of policies and practices to improve writing instruction at any grade level, however, must be grounded in a clear understanding of how writing is currently taught. Without such information, it is hard to determine what needs to be done. The present study addresses this need, as it examined how writing is taught in Grades 1–3, drawing on a random sample of teachers from across the United States. We consider our findings in terms of their implications for future writing instruction for young children. This includes drawing new recommendations as well as examining the value of existing recommendations (specifically from the National Commission on Writing, 2003).

## *How Is Writing Taught in the Primary Grades?*

We hypothesized that primary grade teachers would report applying an eclectic approach to writing instruction, combining instructional procedures from both the process writing and skills approach. These are the most common approaches to teaching writing to young children in the United States (Applebee & Langer, 2006; Graham et al., 2002). With the process approach, considerable attention is placed on the act of writing, emphasizing extended opportunities to write for real audiences, creating a supportive writing environment, encouraging high levels of student interactions around writing, stressing personal responsibility for writing (including self-reflection and evaluation), and engaging in cycles of planning, translating, and revising (Pritchard & Hon-eycutt, 2006). The teaching of writing skills and strategies, however, is often personalized and provided when the need arises (although Nagin, 2003, for example, included sentence combining instruction in process writing). In contrast, writing skills instruction (sometimes referred to as *traditional instruction*) mainly emphasizes the explicit and systematic teaching of handwriting, spelling, sentence construction, and so forth, with writing itself receiving more or less attention depending upon the teacher.

Some professionals (see Freedman, 1993; Smith, 1994) have argued that approaches like process writing, which rely on informal and incidental learning methods, should not be combined with more traditional skills instruction. We anticipated, however, that teachers would favor a more balanced eclectic approach to writing instruction. This was the case when the teachers of young children reported how they taught the related skill of reading (see Baumann, Hoffman, Moon, & Duffy-Hester, 1998), described their beliefs about writing instruction (Graham et al., 2002), and indicated how they taught writing (Graham et al., 2003). The findings from the current study supported this prediction and corroborated the findings from the previous national survey of writing practices conducted by Graham et al. (2003).

In this study, almost 3 out of every 4 teachers indicated that they used a process approach combined with traditional skills instruction. These data taken alone are relatively weak, as process writing and traditional skill instruction were not defined in the survey. However, this combined approach was further reflected in the teachers' reported application of specific instructional practices. The typical teacher placed considerable emphasis on teaching basic writing skills, as spelling, grammar, capitalization, and punctuation skills were reportedly taught daily, with handwriting and sentence construction skills taught several times a week. The typical teacher also reported using a variety of practices common to the process writing approach. This included having students plan (at least weekly) and revise their compositions (at least several times a month), conference with and help other students with their writing (at least several times a month), share their writing with classmates (at least weekly), monitor their writing progress (at least weekly), choose their own writing topics (at least half the time), work at their own pace (at least half of the time), and use invented spellings (most of the time). Although Graham et al. (2003) did not ask teachers about three of these activities (i.e., sentence construction, student/student conferences, and teacher monitoring of students' progress), the teachers in the prior study indicated using six of these practices (i.e., grammar instruction, capitalization/punctuation instruction, student planning, student

sharing, student choice, and invented spelling) as frequently as teachers in this investigation. Teachers in the prior study, however, reported providing spelling instruction less often than teachers in this investigation (weekly vs. daily), but indicated that student revising (weekly vs. several times a month), peers helping each other (weekly vs. several times a month), and students working at their own pace (more than one half the time vs. one half the time) occurred more frequently. These differences are not large and may simply reflect differences in the samples surveyed.

The finding that most teachers applied both process and traditional skill instruction does not mean they applied each equally. Practices associated with traditional skill instruction occurred more often than those associated with the process writing approach (see above). We address the issue of how much emphasis teachers placed on process and skills as well as writing later (under *Additional Recommendations*).

It is interesting to note that teachers reported using most of the instructional practices that we identified. Ninety percent of the teachers reported using 3 out of every 4 practices at least sometime during the year (90% of the teachers used 19 of the 20 practices surveyed in Graham et al., 2003). There was, however, considerable variability in terms of how often a practice was applied (which was also the case in Graham et al., 2003). While we can only speculate on why some teachers readily apply a practice and others do not (e.g., teachers may differ in their views on the value of a particular technique), these findings are troublesome. It may not be enough to introduce teachers to new writing practices and encourage them to apply them. Efforts to reform writing instruction are likely to fall short, if little attention is devoted to how frequently practices are implemented. This needs to be the focus of both preservice as well as inservice professional development efforts.

We did not ask teachers participating in this study if they provided different instruction for different types of students, such as students with learning disabilities or students who were English language learners. This needs to be examined in future research.

### *Support for the Recommendations of the National Commission on Writing*

*Increase the amount of time students spend writing.* The findings from the present study address four recommendations, at least at the primary grade level, for writing instruction reform offered by the National Commission on Writing (2003). One of the commission's recommendations was to increase (i.e., double) the amount of time students spend writing. The median time teachers reported that their students spent writing each day was about 20 min (this involved writing material at least paragraph length or longer). In Graham et al. (2003), the median time was 30 min a day (but included any type of writing—not just paragraph length or longer). In both studies, a remarkably small percentage of the school day was devoted to writing in either study, providing support for the commission's recommendation. Two possible avenues for increasing amount of writing are to have children write more at home and write more often when working on other subjects (more than half of the participating teachers did this just once a week or less in this study).

The data from this study also provide support for a collateral recommendation regarding increased writing: Primary grade stu-

dents should spend more time writing expository text. The most common writing activities in the participating teachers' classes focused on narrative writing (stories, personal narratives, and poems), writing to communicate (letters), completing worksheets, and responding to material read. Expository writing activities, such as writing to inform or persuade, were much less common. However, recent intervention studies demonstrate that even struggling writers in second and third grade can learn to successfully carry out such writing assignments (Graham, Harris, & Mason, 2005; Harris, Graham, & Mason, 2006).

*Make technology a more integral part of teaching writing.* The National Commission on Writing (2003) also recommended that technology should be a more integral part of writing instruction. This includes enhancing the technology infrastructure for writing in schools (hardware and software), as well as training teachers and students to use existing and new technology. While we only examined one aspect of this recommendation—students' use of computers during the writing period—the findings are startling. Students did not use computers during the writing period in 42% of the participating teachers' classrooms, and they only used them several times a year in another 25% of cases. These findings are even more disquieting than the statistics from an earlier national survey (Graham et al., 2003) where 30% of primary grade teachers reported never using computers during the writing period, and 16% reported using them just several times a year. There is ample evidence that computers can enhance the quality of children's writing (Bangert-Drowns, 1993; Goldring, Russell, & Cook, 2003; Graham & Perin, 2007a, 2007c). Thus, the limited use of computer in this and the previous survey by Graham et al. (2003) reinforces the call to make technology a more integral part of writing instruction, at least for primary grade children. It must also be noted that the use of computers is surely related to the number of computers in each class or school. While efforts to increase both hardware and software in schools have been ongoing, they "are often inadequate and frequently unequal" (National Commission on Writing, 2003, p. 23).

*Improve the preparation of teachers.* Another recommendation of the National Commission on Writing (2003) was that teachers need to be better prepared to teach writing. On a positive note, most of the teachers in this study moderately agreed that they were effective teachers of writing, liked to teach writing, and liked to write. When asked about the quality of their college teacher certification program, 28% indicated that it did a very good to exceptional job in preparing them to teach writing. However, another 28% indicated that their preparation was poor or inadequate, with an additional 44% noting that it was adequate. Clearly there is room for improvement. Thus, these findings provide tentative support for a recommendation that teacher education programs need to do a better job of preparing certification students to teach writing to primary grade students.

*Monitor students' writing progress.* The National Commission on Writing (2003) further recommended that students progress in writing be monitored and that assessments are aligned with standards and the curriculum, involve actual writing (not multiple-choice items), and are fair as well as authentic. In this study, we only focused on assessment at the classroom level. Approximately, 2 out of every 3 teachers reported that they monitored their students' writing weekly and had students monitor how they were doing as well. Only 9% of the teachers reported that they

never monitored progress or only did it several times a year. While these findings do not address how progress was monitored or if such monitoring was aligned to standards and the curriculum, they do suggest that teachers view assessment as an important part of their writing program. Additional research is needed, however, to better understand what and how primary grade teachers' assess writing.

### *Additional Recommendations*

**Balance.** The findings from this study provide the basis for three additional recommendations for improving primary grade writing at the classroom level. One area of concern involves the balance between teaching basic writing skills (e.g., handwriting, spelling, grammar, punctuation, and capitalization), teaching writing strategies and processes (e.g., planning, text organization, and revising), and writing text. Students in the typical classroom in this study spent about 1 hr per day writing or receiving writing instruction (based on median statistics and teacher reports). Almost 50% of this time was spent on the teaching of basic writing skills, 35% on writing, and 16% on teaching planning and revising (the percentages for medians are virtually identical in Graham et al., 2003). As we noted earlier, students are not spending enough time writing connected text, and we would also argue that the teaching of planning and revising strategies and processes are not receiving enough emphasis. Explicitly teaching young students how to plan and revise has a powerful impact on improving their writing (see a recent meta-analysis by Graham, 2006a). Furthermore, the available data call into question the effectiveness of systematically teaching grammar and usage (Andrews et al., 2006; Graham & Perin, 2007a). However, close to one half of the time teachers reported spending on skills instruction involved the teaching of grammar and usage. Drawing on all of these data, we recommend that primary grade writing instruction needs to strike an appropriate balance between writing, teaching skills, and learning writing strategies and processes. While students must learn how to write letters fluently, correctly spell words, and so forth (see Graham & Harris, 2000, for an empirical and theoretical justification for this claim), writing text and learning the strategic processes involved in writing should not be shortchanged.

**Motivation.** The typical teachers in this study reported that they frequently used several practices that should have a positive impact on students' motivation for writing, including allowing students to work at their own pace (at least half of the time), sharing their writing with peers (at least weekly), and modeling their enjoyment or love for writing (at least weekly). Other motivational activities, such as publishing and teachers sharing their writing, occurred much less frequently. In contrast, investigations that have studied exceptional primary grade literacy teachers find that their classrooms are rich with activities and procedures designed to foster motivation for writing (see, e.g., Pressley et al., 2005, 2006). There is also some evidence to suggest that motivation for writing influences writing development (Graham, 2006b; Graham, Berninger, & Fan, 2007). Accordingly, we recommend that primary grade teachers place greater emphasis on fostering students love and enjoyment of writing.

**School/home connections.** As a group, the teachers in this study did not report making strong connections for writing between school and home. The majority of teachers reported assign-

ing writing homework once a month or less. In addition, most teachers rarely (several times a year or less) indicated they communicated with parents about their child's writing progress, asked parents to listen to something the child wrote, or asked the child to write at home with their parents. As a result, we recommend that primary grade teachers develop strong school/home relationship designed to foster students' writing development.

### *Summary*

The present study was based on the assumption that primary grade teachers are aware of the elements of their teaching and can relate this knowledge to questions about how they teach writing. Although there is evidence that teachers can provide an accurate description of their literacy practices (see, for instance, Bridge & Hiebert, 1985; DeFord, 1985; Pressley et al., 1996) and we have some preliminary evidence that teachers' responses to the items on this survey accurately reflect what they do in the classroom (see Lane et al., 2008; Olinghouse, 2008), the findings from the current study need to be replicated, as well as supplemented by research where practices are observed and not just reported.

It must also be acknowledged that teachers' responses may be colored by their susceptibility to respond in socially desirable ways (i.e., to indicate they are doing something they are not because the former response would reflect poorly on their teaching). While this did not appear to be the case for some practices (e.g., making school/home connections occur infrequently even though this is a commonly recommended practice in education), it does not rule out this possibility with other items. Thus, this supports the need for additional research that applies observational techniques to the study of the writing practices of primary grade teacher (the lack of such data is a limitation in the current investigation). Nevertheless, this study is the only available contemporary investigation that looks at primary grade writing instruction nationwide, providing needed information for determining what needs to be done to improve writing instruction for young children. Although a prior study by Graham et al. (2003) surveyed primary grade teachers throughout the United States, it focused much more narrowly on how teachers adapted instruction for struggling writers.

The fact that teachers were randomly selected nationwide, a 61% return rate was obtained, and there was evidence that the responders and nonresponders were similar on selective variables (grade taught, type of school, location of school, size of school, and expenditures for commercial materials per student) diminishes concerns about response bias. It is important to note, however, that these safeguards do not completely alleviate this concern, as other factors, such as their disposition toward the teaching of writing, may have distinguished responders from nonresponders.

It must further be noted that for the 41 eight-point Likert-type items, sampling error was  $\pm 4.9\%$  given the size of the population, the number of participants completing the survey, the expected variation in teacher responses, and a statistical confidence level of 95%. However, for items that involved a yes/no response (e.g., the application of specific writing assignment, such as story writing), the sampling error was larger ( $\pm 7.3\%$ ). In addition, considerable caution must be applied to any findings concerning specific grade-level effects, as the sampling error is even greater.

It is also important to note that the present study just focused on classroom practices. We did not examine other factors, such as

school-wide, district, or state policies, that shape writing instruction. Furthermore, we did not examine all possible aspects of classroom writing practices. This would be impossible in a survey study, as very few teachers would be willing to complete such a questionnaire. We attempted to address this issue by drawing on previous research as well as expert recommendations for teaching writing when developing items to assess classroom practices, but our findings and recommendations must be interpreted in light of these limitations.

In summary, we found that most primary grade teachers take an eclectic approach to writing instruction, combining elements from the two most common methods for teaching writing: process writing and skills instruction (although they generally place less emphasis on process writing). In addition, almost all teachers reported using most of the practices surveyed, but there was considerable variability between teachers in how often they applied each practice. This finding yields an important implication for reform efforts. Such efforts will need to go beyond teachers just learning and applying new procedures and focus on how frequently new practices are applied.

The findings from this study and to a lesser extent Graham et al. (2003) also provide some directions for what needs to be done to reform writing instruction. Primary grade students need to spend more time writing, including writing expository text. There needs to be a better balance between time spent writing, learning writing process and strategies, and teaching writing skills, with more emphasis placed on the first two elements. Teachers need to pay more attention to promoting students' love and motivation for writing. Stronger connections for writing between school and home need to be established. Computers also need to become a more integral part of the writing program at the primary levels. Finally, teacher education programs need to do a better job of professional development in the teaching of writing to young children.

# Epistemological Beliefs' Contributions to Study Strategies of Asian Americans and European Americans

Marlene Schommer-Aikins  
Wichita State University

Marilyn Easter  
San Jose State University

Given the increasingly culturally diverse composition of students in American classrooms, understanding the nature of cultural differences is necessary to generate effective instructional interventions. This study examines the individual differences in epistemological beliefs, ways of knowing, study strategies, and academic performance among different cultural groups. These cultural groups include European Americans (Americans of European ancestry) and first and successive generations of Asian Americans. College junior and senior business majors completed instruments assessing epistemological beliefs, ways of knowing, and study strategies. Multivariate analyses of variances revealed significant differences among cultural groups in 5 study strategies (low anxiety, selecting main ideas, testing strategies, high motivation, and information processing), course grades, and reading comprehension. Regression analyses revealed that beliefs about learning speed, knowledge construction, characteristics of successful students, and separate knowing contributed to cultural differences. This study highlights the need to avoid strong stereotyping and to consider individual differences in the classroom.

**Keywords:** epistemological beliefs, cultural differences, study strategies, reading comprehension, Asian American

Since 1990, students' epistemological beliefs (beliefs about the nature of knowledge and learning) have been studied using a multidimensional paradigm (Schommer, 1990). Within this paradigm, researchers have examined beliefs about the structure of knowledge, the sources of knowledge, the certainty of knowledge, the speed of learning, and the ability to learn (Buehl, Alexander, & Murphy, 2002; Hofer, 2000; Jehng, Johnson, & Anderson, 1993). The accumulating evidence indicates that epistemological beliefs predict comprehension, metacomprehension, and academic performance (Schommer-Aikins, 2004). In this study, we compare the epistemological beliefs and study strategies of first and successive generations of Asian Americans and European Americans (Americans of European ancestry). We examine how these individual difference variables may contribute to cultural differences.

It is important to understand cultural differences through the lens of individual differences. To state that students in the class perform differently because they are from different cultures is insufficient. Instead, we should ask, "Specifically what about the cultures is making the difference?" Cultures differ in beliefs, norms, and behavior. Our focus is the difference in beliefs among cultures. We argue that these differences in beliefs (epistemology) are likely to lead to differences in cognition (study strategies) and subsequently to differences in academic performance.

We further argue that instructors may misinterpret students' behavior if they focus on cultural stereotypes rather than individual differences. For example, if students do not ask questions or participate in classroom discussions, this silence is open to the instructor's interpretation. Silence could be interpreted as a sign of understanding (based on a positive stereotype), or silence could be interpreted as a sign of lack of understanding or indifference (based on a negative stereotype; Chang & Demyan, 2007; Ng, Lee, & Pak, 2007). If instructors rely on stereotypes rather than on monitoring student understanding in multiple ways, students may not receive the academic support that they need.

## Consequences of Stereotypes

This study is an initial attempt to test our assertions. We tested for differences in beliefs and study strategies between cultures. We then tested the notion that epistemological beliefs and study strategies contribute to differences in academic performance.

Some cultural stereotypes can be misleading—for example, the "model minority." The U.S. news media assigned the term model minority to successful Asian Americans, presumably as a compliment and a source of inspiration to others (Kao, 1995; Tasaki, 2001), but the residual consequences to Asian Americans have been mixed (Lee, 1994). On the surface, this stereotype might seem advantageous. When Asian Americans are seen as hardworking and valuing education, others assume that they will excel in most academic subjects. However, this stereotype is an overgeneralization that is difficult to cope with if one does not meet the projected expectations.

For example, Lee (1994) portrays the burden and inappropriateness of the model-majority stereotype among Asian American high school students. First, it is presumptuous to categorize all Asian Americans into a single group. Asian Americans come from dif-

ferent countries, different socioeconomic groups, and different parenting styles. Second, Asian Americans are aware of the stereotype and may react differently to this characterization. In Lee's ethnographic study, four different student reactions were identified. Students reacted by doing one or more of the following: (a) distancing themselves from other Asians, (b) choosing less desirable careers, (c) interpreting a less-than-perfect academic performance as a failure, or (d) doing just enough academic work to get by.

In Lee's (1994) study, some students identified themselves as Korean. They distanced themselves from other Asians and were encouraged by their parents to emulate upper-middle-class European Americans outside the home to achieve success. Yet, at the same time, their parents encouraged them to maintain their Korean identity within the home and within Korean community events. Despite the positive attitude toward success, Korean students in this sample had varying levels of academic success. In response to this varying academic success, the higher achievers willingly helped the lower achievers.

The academic behavior of students who identified themselves as Asian was most consistent with the stereotype of the quiet, hard-working student (Lee, 1994). Their parents taught them that doing well in school was the key to success. Despite that optimistic view of school, Asian-identified students anticipated discrimination in the United States, particularly because of their accents. Students would often select careers that were less desirable to avoid rejection on the basis of language. For example, students who truly wanted to study law might go into engineering instead to avoid issues about accents. In Lee's (1994) study, although these students valued hard work and education, their academic achievement ranged from high to low.

Students who identified themselves as Asian American considered themselves neither exclusively Asian nor American (Lee, 1994). Rather, they had a new identity that was a blend of Asian and American. They also believed in hard work and doing well in school to fight racism. They were outspoken about racism by speaking out against the model-minority stereotype. For example, they argued that if Asian American students were not at the very top of their math class, they were considered failures. This put undue pressure on students who under other circumstances would have been considered to be performing well.

Asian American students who identified themselves as New Wavers took this term from New Wave music (Lee, 1994). These high school students made their identity and group membership obvious with their spiked hair and black clothes. Unlike other Asian Americans, they did not define success through school performance. Indeed, they blatantly disrespected academic rules to assume an identity that was the opposite of the expected stereotype, doing just enough work to pass their courses. Notions of future careers were vague. Allegiances were aligned more to their peers than to the aspirations offered by their parents or the school system. Aspirations were aimed more at physical prowess or beauty than academic achievement. Indeed, academic achievers were seen as "nerds," a label they did not want to endorse by actually doing well in school. In summary, Lee's work suggests that Asian American students' identities, motivation, and academic achievement varies greatly.

Finally, there is evidence that academic performance among cultural groups is not consistent with the model-minority hypoth-

esis when the academic tasks require creativity and open-ended thinking. Recently, Wang and Lin (2005) highlighted that cross-cultural studies on American and Chinese students regarding mathematics learning may be misleading. For example, Chinese students routinely outperform U.S. students in computational skills and routine problem-solving skills in mathematics. Less well known is that U.S. students typically outperform Chinese students on open-ended and creative problem-solving tasks (Cai, 1997, 1998, 2000). Wang and Lin attempted to generate potential explanations for the mixed findings; the dominant explanation was that classifying participants as Asian American masks a large variability within that group. There is immense diversity in the nation of origin, as well as language and social adjustment. Furthermore, there is a disparity between Asian Americans' mathematical performance and verbal performance. Wang and Lin suggested examining more individual difference variables within and between cultures and exploring more specific performance measures.

### Epistemically Related Beliefs

In this study we focus on an array of beliefs: some that are traditionally considered epistemological, such as belief in the certainty and structure of knowledge, and some that have only recently been considered intimately related to epistemology, such as belief in ways of knowing (Schommer-Aikins, 2004). Therefore, we refer to the beliefs examined in this study as *epistemically related beliefs*, which include beliefs about the nature of knowledge and learning (epistemological beliefs, Schommer, 1990) and ways of knowing (Belenky, Clinchy, Goldberger, & Tarule 1986). Epistemically related beliefs are thought to guide students' choices of study strategies and subsequently their academic performance. One's culture may contribute to epistemically related beliefs (Schommer-Aikins, 2004). For example, the more children are given an opportunity to question and discuss important issues with their parents, the more likely they are to believe that learning is a gradual process. Moreover, the more postsecondary education adults receive, the more likely they are to believe knowledge is tentative and complex (Schommer, 1994). Hence, both individual and larger, cultural perspectives likely inform epistemically related beliefs.

Perry's (1968) work on students' views about education initiated a general interest in epistemological beliefs. His interviews with Harvard undergraduate men led him to theorize that freshmen enter college believing that knowledge is simple, certain, and handed down by authority. In contrast, Perry found that seniors believed that knowledge is complex, tentative, and derived from reason based on evidence. Although many researchers developed lines of epistemic research closely aligned to Perry's thinking (e.g., Baxter Magolda, 1987; Kitchener & King, 1989; Ryan, 1984), two lines of research forged other paths of study.

One epistemic path was forged by Belenky et al. (1986), who were concerned that Perry's work was based mainly on a male population. Hence, in contrast to Perry, they conducted extensive interviews with women, from whom they theorized epistemic positions known as *ways of knowing*. More recent articulation of their work (Clinchy, 2002) focuses on two major epistemic positions, *separate knowing* and *connected knowing*.

Research indicates that both ways of knowing contribute to deeper thinking, each taking a different path to meet similar goals.

Individuals who emphasize separate knowing take the “devil’s advocate” approach. They doubt and question first, then attempt to embrace new ideas. Individuals who emphasize connected knowing take an empathic approach. They try to take on others’ roles to see the world from their perspective and to understand first, then engage in more evaluative thinking.

Studies (Clinchy, 2002; Galotti, Blythe, Ainsworth, Lavin, & Mansfield, 1999) have found these ways of knowing are gender related in the United States; men have a propensity toward separate knowing, and women have a propensity toward connected knowing. In other words, men tend to play the devil’s advocate, whereas women are more likely to think empathically. This does not imply, however, that these ways of knowing are gender specific. Indeed, individuals are arguably capable of both ways of knowing. Clinchy (2002) hypothesized that the most advanced thinkers have learned to use each way of knowing adaptively to meet situational demands.

Another epistemic path that moved beyond Perry’s work was forged by Schommer (1990). On the basis of a synthesis of research from 1968 to 1988 (e.g., Baxter Magolda, 1987; Dweck & Bempechat, 1983; Kitchener & King, 1981; Perry, 1968; Ryan, 1984; Schoenfeld, 1983), Schommer proposed the idea of an epistemological belief system. In this case, *system* means that personal epistemology is composed of a number of more or less independent belief dimensions; *independent* means that these beliefs do not necessarily mature at the same rate. These beliefs included the stability (from unchanging to evolving), structure (from isolated facts to integrated complexities), and source of knowledge (from handed down by authority to derived from reason and evidence); the speed of learning (from quick or not at all to gradual); and the ability to learn (from fixed at birth to incremental). The implication is that to understand individuals more completely, it is important to assess all of their beliefs. As a result of these recent developments in measurement, researchers continue to find important links between epistemological beliefs and various aspects of learning. Epistemological beliefs predict comprehension, metacomprehension, and interpretation of information (Schommer-Aikins, 2004).

The consequences of epistemological beliefs are arguably subtle because many of their effects are mediated by other variables (Bendixen & Rule, 2004; Schommer-Aikins, 2004). For example, if students believe that knowledge is structured as isolated facts, they will likely study by memorizing lists of concepts. In the classroom, students will recall words and/or definitions, but they will lack applicable or contextual understanding. To date there are few studies on the mediating effects of epistemological beliefs (e.g., Schommer, Crouse, & Rhodes, 1992; Schommer-Aikins, Duell, & Hutter, 2005; Schreiber & Shinn, 2003). Furthermore, these studies have focused on fairly homogeneous populations.

### Cross-Cultural Study of Epistemically Related Beliefs

Limited research has examined the multidimensional epistemological belief system in cross-cultural studies. Some researchers have explored the specific dimensions that constitute the personal epistemology of Chinese students and have found epistemological belief factors that merge (e.g., simple–certain; Qian & Alvermann, 2000) or factors composed of different nuances (e.g., omniscient authority shifting on factors; Chan & Elliott, 2002). The precise

nature of epistemological beliefs within cultures, as well as between them, remains unknown.

Qian and Pan (2002) compared American and Chinese 11th and 12th graders. They found that Chinese students were more likely to believe in simple knowledge and innate ability than American students. Karabenick and Moosa (2005) similarly found that Middle Eastern (Omani) students were more likely to believe that knowledge is simple and certain than American students. Omani male students were more accepting of omniscient authority than Omani female students were. No gender differences regarding epistemic beliefs were found with the American students in Karabenick and Moosa’s study.

In our work, comparisons of epistemological beliefs were made between European Americans (EUROA), first-generation Asian Americans (FIRSTAA), and beyond-first-generation Asian Americans (BEYONDAA). Distinctions between first-generation and beyond-first-generation Asian Americans were made because cultural differences from the mainstream are typically reduced in subsequent generations (Rozin, 2003). We investigated the roles that epistemological beliefs and study strategies play in academic performance involving open-ended and creative responses, because investigations of these types of academic tasks are limited in cross-cultural studies. We hypothesized that epistemological beliefs, ways of knowing, and study strategies are three arrays of individual difference variables that account for cultural differences.

In this study four hypotheses were tested:

*Hypothesis 1:* Cultural groups will differ in their epistemological beliefs and ways of knowing. Specifically, EUROA will have higher scores on epistemological beliefs.

*Hypothesis 2:* Study strategy differences will be explained by epistemological beliefs, ways of knowing, and/or gender. Specifically, if study strategy differences are found among cultural groups, epistemological beliefs and ways of knowing will contribute to those differences.

*Hypothesis 3:* Cultural groups will differ in nonmathematical academic performance. Specifically, EUROA will score higher on academic performances that require open-ended and creative responses.

*Hypothesis 4:* Academic performance differences between groups will be partially explained by study strategies, epistemological beliefs, ways of knowing, and gender. Specifically, at least part of the variance due to cultural differences will be accounted for by individual differences.

### Method

#### Participants

Participants were 264 college juniors ( $n = 151$ ) and seniors ( $n = 113$ ) enrolled in a business communication class at a West Coast U.S. university. There were 88 FIRSTAA (57% female, 43% male), 90 BEYONDAA (57% female, 43% male), and 78 EUROA (51% female, 49% male). The average age was 24 years old ( $SD = 5.61$ ), with a range of 19 to 54 years old. The youngest group was BEYONDAA ( $M = 22.54$ ,  $SD = 3.21$ ). The next

youngest group was FIRSTAA ( $M = 24.31$ ,  $SD = 4.47$ ). The oldest group was EUROA ( $M = 25.97$ ,  $SD = 7.99$ ). There was one significant difference in age between BEYONDAA and EUROA:  $F(2, 247) = 7.89$ ,  $p < .01$ ,  $\eta^2 = .06$ . Students were asked if English was their first language; 26.1% of FIRSTAA, 51.1% of BEYONDAA, and 94.9% of EUROA responded "yes." Students received extra credit for their participation in the study.

### Instruments

**Study strategies.** Study strategies were assessed using the Learning and Study Strategies Inventory (LASSI; Weinstein & Palmer, 2002). This instrument assesses study strategies related to technique, motivation, and self-regulation. Subtests and sample items include the following: low anxiety about academic performance (Low Anxiety), "Worrying about doing poorly interferes with my concentration on tests" (reverse scored); positive attitude toward school (Positive Attitude), "I feel confused and undecided as to what my educational goals should be" (reverse scored); concentration (Concentration), "I concentrate fully when studying"; information processing (Information Processing), "I translate what I am studying into my own words"; high academic motivation (High Motivation), "I set high standards for myself in school"; selecting main ideas (Selecting Main Ideas), "I have difficulty identifying the important points in my reading"; self-testing (Self-Testing), "I stop periodically while reading and mentally go over or review what was said"; use of study aids (Study Aids), "I use special helps, such as italics and headings, that are in my text"; test strategies (Test Strategies), "I have difficulty adapting my studying to different types of courses" (reverse scored); and time management (Time Management), "When I decide to study, I set aside a specific length of time and I stick to it." Subtests were composed of eight items each with the exception of Selecting Main Ideas, which was composed of five items. This is a field-tested instrument with over 1,000 students represented. Weinstein and Palmer (2002) reported that Cronbach's alpha for subscales ranged from .73 to .89.

**Epistemically related beliefs.** Ways of knowing were measured with the Attitude Toward Thinking and Learning Survey (ATTLS; Gallotti et al., 1999). This 20-item questionnaire generates unique scores for Separate Knowing and Connected Knowing composed of 10 items each. Students respond to statements such as "I try to think with people instead of against them," and "I like playing the devil's advocate arguing the opposite of what someone is saying." They were measured on a Likert scale from 1 (*strongly disagree*) to 7 (*strongly agree*). Gallotti et al. (1999) reported Cronbach's alpha from each scale of .83 (Connected Knowing) and .77 (Separate Knowing). Details of psychometric properties and instrument development can be seen in their report.

Epistemological beliefs were measured using the Kardash Epistemological Belief Scale (Kardash & Wood, 2000; Wood & Kardash, 2002). This questionnaire evaluates student beliefs about the speed of knowledge acquisition (Speed), composed of eight items ranging from "quick all-or-none learning" to "learning is a gradual process that takes effort"; the structure of knowledge (Structure), composed of 11 items ranging from "knowledge is organized as isolated facts" to "knowledge is structured in integrated, complex, and sometime ambiguous concepts"; knowledge construction and modification (Construction), composed of 11 items ranging from

"knowledge is certain and passively received" to "knowledge is constantly evolving and it takes active modification and personal construction to learn"; characteristics of successful students (Success), composed of five items ranging from "good learners have innate ability and are able to memorize and learn with ease" to "although good learners have acquired study skills, learning still takes time and effort"; and attainability of truth (Truth), composed of three items ranging from "there is objective truth attainable by scientists" to "there are seldom single answers and facts/truths should be open to question." Students responded to statements such as "Usually, if you are ever going to understand something, it will make sense to you the first time" (Speed, reverse scored); "I like information to be presented in a straightforward fashion. I don't like having to read between the lines" (Structure, reversed score); and "Wisdom is not knowing the answers but knowing how to find the answers" (Construction). Items were measured on a Likert scale from 1 (*strongly disagree*) to 5 (*strongly agree*). Kardash and Wood (2000) reported that Cronbach's alpha for these belief scales ranged from .54 to .74. Details of psychometric properties and instrument development can be seen in Wood and Kardash (2002).

In a previous study (Easter & Schommer-Aikins, 2004), all of the described instruments were pilot-tested for this population. Students were instructed either to ask the researcher questions or to write comments next to items that were unclear. Students indicated that all instruments were easy to understand.

These beliefs and study strategies, as conceived in existing studies, have been shown to predict academic performance in U.S. schools. Because this study was conducted in U.S. schools, scores were calculated using formulas from the authors of the instruments. This does not suggest that we believe that these scores reflect cultural nuances of each group. Rather, these beliefs likely are important for success in the U.S. schools.

**Academic performance.** Two measures of academic performance were obtained. All business communication students were required to take the Reading Comprehension test from the NCS Pearson (2000) Reading and Arithmetic Indexes-12. This test assesses word decoding, phrase comprehension, sentence comprehension, and paragraph comprehension. For example, a typical item for sentence comprehension would be as follows: "A man in Texas, trying to call Iowa City, dialed the wrong number." Students then select from several options such as the following: (a) "The man dialed the wrong number in Iowa"; (b) "The man, while trying to dial Iowa City, dialed the wrong number"; (c) "The man called Texas instead of Iowa City"; and (d) "The man could not call Texas or Iowa City." This instrument assesses basic reading commonly required for entry-level employment, including office/clerical, vocational, and manufacturing jobs. Scores can range from 1 to 72. Test-retest reliabilities for this reading test range from .86 to .93 (NCS Pearson, 2000). Details of psychometric properties are reported in the NCS Pearson (2000) manual for the test.

Student course grades for the business communication class were also used as a measure of academic performance. Throughout the semester, instructors provided students with feedback on more than 30 pages of written assignments. Instructors also evaluated students through midterm and final exams, weekly quizzes, in-class writing exercises, and verbal discussions. All instructors used

consistent grading criteria for assignments. Final grades for this study were coded numerically from 0 (F) to 12 (A).

**Demographics.** Basic demographic information was assessed as well. Students were asked to report their age, gender, and ethnicity. They were also asked if English was their first language—that is, the primary language they used regularly.

### Procedure

Surveys were administered by classroom instructors over a 4-week period. The sequence of the survey's administration was counterbalanced to control for possible order effects. Surveys were completed at the beginning of each class, before any other activities. Half of the class received one survey (e.g., ATTLS), and the remaining students in the class completed a different survey (e.g., LASSI). Each survey took approximately 15–30 min to complete.

### Results

**Scores for each measure.** Scores were calculated for each survey instrument, and interitem correlations of Cronbach's alpha were calculated for each cultural group. Cronbach's alpha for this study was similar to previous studies (see Wood & Kardash, 2002). In the study being reported, Cronbach's alpha for LASSI ranged from .59 to .81, ways of knowing ranged from .60 to .81, and epistemological beliefs ranged from .50 to .82. Cronbach's alpha for each measure broken down by cultural group are shown in Table 1. For all scores in this study, higher scores represent better support for learning. For example, a high score on the Low Anxiety scale means that the student can cope with anxiety well. A high score on Speed means that the student believes learning may require more time to complete.

**Epistemological belief differences.** To test the hypothesis that cultural groups differ in their epistemological beliefs, we conducted a two-way multivariate analysis of variance (MANOVA; Cultural Group  $\times$  Gender) using epistemological beliefs scores as the dependent variables. Wilks's lambda multivariate statistic was

Table 1  
Cronbach's  $\alpha$  for Epistemological Beliefs and Ways of Knowing

Variable	FIRSTAA	BEYONDAA	EUROA
Structure	.50	.53	.64

Select Main Ideas	.86	.85	.91
Study Aids	.72	.59	.63
Time Management	.82	.81	.85
Test Strategies	.79	.79	.83

Note. FIRSTAA = first-generation Asian Americans; BEYONDAA = beyond-first-generation Asian Americans; EUROA = Euro-Americans.

significant for cultural groups:  $F(10, 466) = 6.59, p < .001, \eta^2 = .12$ . Univariate analyses indicated two significant main effects for cultural groups in Speed,  $F(2, 236) = 18.39, p < .001, \eta^2 = .14$ , and Structure,  $F(2, 236) = 11.80, p < .001, \eta^2 = .09$ . Follow-up Tukey post hoc tests indicated the EUROA had significantly higher scores for Speed compared to both FIRSTAA,  $F(1, 158) = 40.99, p < .001, \eta^2 = .20$ , and BEYONDAA,  $F(1, 159) = 19.20, p < .001, \eta^2 = .11$ . EUROA also had significantly higher for Structure compared to both FIRSTAA,  $F(1, 157) = 16.09, p < .001, \eta^2 = .09$ , and BEYONDAA,  $F(1, 158) = 18.39, p < .001, \eta^2 = .10$ . In other words, the EUROA group had a stronger belief that learning takes time and that knowledge is organized as a complex network. There were no significant differences between the two Asian American groups (FIRSTAA and BEYONDAA). Descriptive statistics for epistemological beliefs are shown in Table 2.

**Ways of knowing differences.** To address the hypothesis that cultural groups differ in their ways of knowing, another two-way MANOVA (Cultural Group  $\times$  Gender) was conducted with Separate Knowing and Connected Knowing scores as dependent variables. Wilks's lambda multivariate statistic was significant for gender,  $F(2, 249) = 16.32, p < .001, \eta^2 = .12$ . Women had a stronger belief in connected knowing (women,  $M = 55.13, SD = 8.10$ ; men,  $M = 51.37, SD = 8.28$ ),  $F(1, 250) = 14.22, p < .001, \eta^2 = .05$ ; and men had a stronger belief in separate knowing (women,  $M = 43.85, SD = 7.78$ ; men,  $M = 46.21, SD = 8.28$ ),  $F(1, 250) = 4.99, p < .03, \eta^2 = .02$ .

**Study strategy differences.** To address the hypothesis that cultural groups differ in their study strategies, a two-way MANOVA (Cultural Group  $\times$  Gender) was conducted with the LASSI scores as dependent variables. Wilks's lambda multivariate statistic was significant for both cultural groups,  $F(20, 450) = 2.50, p < .001, \eta^2 = .10$ , and gender,  $F(10, 225) = 3.80, p < .001, \eta^2 = .15$ . Univariate analyses indicated that cultural groups differed on Low Anxiety,  $F(2, 234) = 4.54, p < .01, \eta^2 = .04$ ; Information Processing,  $F(2, 234) = 4.08, p < .05, \eta^2 = .03$ ; High Motivation,  $F(2, 234) = 6.44, p < .01, \eta^2 = .05$ ; Selecting Main Ideas,  $F(2, 234) = 5.18, p < .01, \eta^2 = .04$ ; and Testing Strategies,  $F(2, 234) = 4.71, p < .01, \eta^2 = .04$ . Follow-up Tukey post hoc tests indicated that EUROA, compared to FIRSTAA, were better able to control their anxiety about school,  $F(1, 156) = 11.82, p < .001, \eta^2 = .07$ ; select main ideas,  $F(1, 156) = 7.56, p < .001, \eta^2 = .05$ ; and prepare for tests,  $F(1, 156) = 8.07, p < .001, \eta^2 = .05$ . Compared to BEYONDAA students, EUROA students were better able to select main ideas,  $F(1, 165) = 10.87, p < .001, \eta^2 = .06$ ; use information processing strategies,  $F(1, 165) = 10.73, p < .001, \eta^2 = .06$ ; and be academically motivated,  $F(1, 165) = 18.44, p < .001, \eta^2 = .10$ . There were no statistically significant differences between the two Asian American groups.

Univariate analyses for gender comparisons indicated that women, overall, were better able to use study aids (women,  $M = 26.03, SD = 4.49$ ; men,  $M = 23.68, SD = 5.07$ ),  $F(1, 234) = 13.70, p < .01, \eta^2 = .06$ ; better able to manage their time (women,  $M = 26.00, SD = 6.04$ ; men,  $M = 24.15, SD = 5.77$ ),  $F(1, 234) = 8.79, p < .01, \eta^2 = .04$ ; and had a better attitude toward school (women,  $M = 32.05, SD = 4.83$ ; men,  $M = 30.75, SD = 4.46$ ),  $F(1, 234) = 5.62, p < .05, \eta^2 = .02$ . Men were better able to control their anxiety about school (women,  $M = 25.02, SD = 7.60$ ;

Table 2  
*Epistemological Beliefs by Cultural Groups*

Belief	Cultural group		
	EUROA <i>M (SD)</i>	FIRSTAA <i>M (SD)</i>	BEYONDAA <i>M (SD)</i>
Speed <sup>a</sup>	4.18 (0.35)	3.72 (0.52)	3.86 (0.54)
Structure <sup>a</sup>	2.85 (0.47)	2.56 (0.41)	2.56 (0.38)
Construction	3.68 (0.36)	3.65 (0.36)	3.67 (0.32)
Success	3.27 (0.75)	3.18 (0.69)	3.33 (0.75)
Truth	3.30 (1.03)	3.06 (0.90)	3.23 (0.81)

Note. EUROA = Euro-Americans; FIRSTAA = first-generation Asian Americans; BEYONDAA = beyond-first-generation Asian Americans.

<sup>a</sup>EUROA had significantly higher belief scores compared to both Asian American groups.

men,  $M = 27.47$ ,  $SD = 6.01$ ),  $F(1, 234) = 6.25$ ,  $p < .05$ ,  $\eta^2 = .03$ . Descriptive statistics for the LASSI are shown in Table 3.

*Epistemological beliefs and ways of knowing as predictors of study strategies.* To test the hypothesis that epistemological beliefs and ways of knowing explain some of the cultural differences in study strategies, regression analyses were conducted. Each LASSI variable that was significant (for cultural differences) in the previous findings served as a dependent variable. In the first block of variables to enter the equation, epistemological beliefs, ways of knowing, and gender competed for entry, if significant at the .05 level. The second block of variables that entered the equation, if significant at the .05 level, was the appropriate contrast, either EUROA versus FIRSTAA or EUROA versus BEYONDAA. A summary of these regressions is shown in Table 4.

For the EUROA versus FIRSTAA comparison, differences between cultural groups on LASSI variables were accounted for by epistemological beliefs, ways of knowing, and gender. Specifically, Speed and gender predicted Low Anxiety. The more students believed learning is gradual, the less anxiety they reported. Men reported less anxiety than women did.

Speed, Separate Knowing, and Success predicted Selecting Main Ideas. The more students believed that learning is gradual, believed in separate knowing, and believed that success is related to hard work, the more likely they were to report that they could identify main ideas.

Speed and Separate Knowing predicted Testing Strategies. The more students believed that learning is gradual and believed in separate knowing, the more likely they were to report preparing for tests strategically. Cultural differences were no longer significant.

For the EUROA to BEYONDAA comparison, differences in LASSI variables were partially accounted for by epistemological beliefs and ways of knowing. A summary of these regressions is shown in Table 5. Specifically, Speed predicted Selecting Main Ideas. The more students believed that learning is gradual, the more likely they were to report being able to select main ideas.

Speed and the culture contrast predicted High Motivation. The more students believed learning is gradual, the more likely they were to report being academically motivated. EUROA students reported higher academic motivation than BEYONDAA students.

Construction, Separate Knowing, and culture contrast predicted Information Processing. The more students believed that certain knowledge is actively acquired and believed in separate knowing,

the more likely they were to report using information processing study strategies. EUROA students reported higher use of information processing strategies than BEYONDAA students did.

*Academic performance differences.* To test the hypothesis that there are differences between cultural groups in academic performance, two-way ANOVAs were conducted with the final course grade as a dependent variable in one analysis and reading scores as the dependent variable in another analysis. Gender and cultural groups served as independent variables. With the final course grade as the dependent variable, there was a main effect for cultural groups,  $F(2, 225) = 6.51$ ,  $p < .01$ ,  $\eta^2 = .05$ . The follow-up Tukey post hoc test indicated that EUROA students outperformed both FIRSTAA students,  $F(1, 147) = 10.37$ ,  $p < .01$ ,  $\eta^2 = .07$ , and BEYONDAA students,  $F(1, 151) = 9.61$ ,  $p < .01$ ,  $\eta^2 = .06$ . There was also a main effect for gender, in which women outperformed men (women,  $M = 8.73$ ,  $SD = 2.72$ ; men,  $M = 8.01$ ,  $SD = 3.29$ ),  $F(1, 225) = 4.51$ ,  $p < .05$ ,  $\eta^2 = .05$ .

With reading scores as the dependent variable, there was a main effect for the cultural groups,  $F(2, 233) = 5.44$ ,  $p < .01$ ,  $\eta^2 = .05$ . The follow-up Tukey post hoc tests indicated that EUROA students outperformed FIRSTAA students,  $F(1, 155) = 11.91$ ,  $p < .001$ ,  $\eta^2 = .07$ . There were no statistically significant differences between the two Asian American groups. Descriptive statistics for academic performance are shown in Table 6.

*Individual differences as predictors of academic performance.* To test the hypothesis that epistemological beliefs, ways of knowing, and study strategies account for cultural group differences in academic performance, hierarchical multiple regression analyses were conducted with the final grade as the criterion variable in one analysis and reading score as the criterion variable in another analysis. In the first block of variables to enter the equation, epistemological beliefs, ways of knowing, LASSI, English as first language, and gender were allowed to enter the equation if they were significant at the .05 level. The second block of variables to enter the equation was the appropriate contrast, either EUROA versus both Asian American groups or EUROA versus FIRSTAA, if significant at the .05 level. A summary of these regressions is shown in Table 7.

Table 3  
*LASSI Scores by Cultural Groups*

Study strategy	Cultural group		
	EUROA <i>M (SD)</i>	FIRSTAA <i>M (SD)</i>	BEYONDAA <i>M (SD)</i>
Low Anxiety <sup>a</sup>	28.11 (7.23)	24.59 (7.32)	26.24 (6.27)
Positive Attitude	32.07 (5.44)	31.27 (4.42)	30.97 (4.29)
Concentration	28.28 (5.19)	26.30 (5.10)	27.16 (4.98)
Information Processing <sup>b</sup>	28.55 (5.54)	28.30 (5.30)	26.43 (4.94)
High Motivation <sup>b</sup>	32.73 (5.58)	30.98 (4.82)	29.88 (4.94)
Self Testing	23.68 (5.55)	24.45 (5.77)	23.52 (5.50)
Selecting Main Ideas <sup>a,b</sup>	30.82 (6.04)	28.22 (5.53)	28.36 (5.09)
Study Aids	24.30 (5.00)	25.79 (5.56)	24.57 (4.76)
Time Management	25.22 (6.84)	25.04 (5.92)	25.47 (5.40)
Testing Strategies <sup>a</sup>	30.44 (5.27)	27.81 (5.45)	29.17 (4.83)

Note. LASSI = Learning and Study Strategies Inventory; EUROA = Euro-Americans; FIRSTAA = first-generation Asian Americans; BEYONDAA = beyond-first-generation Asian Americans.

<sup>a</sup>EUROA scored significantly higher scores than FIRSTAA.

<sup>b</sup>EUROA scored significantly higher scores than BEYONDAA.

Table 4

*Summary of Regression Analyses: Epistemological Beliefs as Predictors of Study Strategies, EUROA versus FIRSTAA*

Criterion variable	Predictor variable	$R^2$	Standardized $B$ weight	$F$ change	Sig.
Low anxiety	Speed	.10	0.32	16.60	.001
	Gender	.03	-0.16	4.24	.05
Select main ideas	Speed	.10	0.33	17.81	.01
	Separate knowing	.03	0.18	5.74	.05
	Success	.02	0.17	4.01	.05
	Speed	.13	0.37	23.15	.001
Testing strategies	Speed	.13	0.37	23.15	.001
	Separate knowing	.03	0.16	4.61	.05

Note. Sig. = significance.

Four factors predicted final course grade: Speed, Concentration, Gender, and Culture Contrast (EUROA vs. both Asian groups). Although beliefs about speed of learning, concentration on academic tasks, and gender contributed to final course grades, cultural differences remained.

Three factors predicted reading scores: Testing Strategies, English as First Language, and Study Aids. In sum, EUROA students differed from FIRSTAA students on reading scores. Cultural differences were eliminated once testing strategies, English as a first language, and use of study aids were entered into the regression.

### Discussion

The most fundamental question addressed in these analyses is: Are there differences in epistemological beliefs and ways of knowing among cultural groups? There were two significant differences. Euro-American students, compared to both Asian American groups, had stronger beliefs that learning is a slow, gradual process and that knowledge is complex. This is consistent with Qian and Pan's (2002) results, in which U.S. high school students believed more strongly that knowledge is complex than did high school students in China.

Additional analyses examined group differences in study strategies and academic performance. First, cultural differences in study strategies were revealed. Compared to first-generation Asian Americans, Euro-American students were better able to control their anxiety about school, select main ideas from texts, and prepare for tests. Compared to beyond-first-generation Asian Americans, European Americans were more able to select main ideas and use information processing strategies and were better academically motivated.

Next, we tested the notion that students' epistemological beliefs, ways of knowing, and gender may account for cultural differences

in study strategies. Results indicated that epistemological beliefs, ways of knowing, and gender contributed to cultural differences in study strategies.

Belief in quick learning contributed to cultural differences in study strategies. Students who scored lower on selecting main ideas, testing strategies, low anxiety, and high motivation were more likely to agree that learning is quick. For example, students who scored lower on these study strategies agreed with study strategy items such as the following: "When I am studying, worrying about doing poorly in a course interferes with my concentration" (Weinstein & Palmer, 2002, p. 9) and "When studying, I seem to get lost in the details and miss the important information" (Weinstein & Palmer, 2002, p. 11). These results suggest that if students believe learning is quick, they are likely to speed through homework and tests. Selecting main ideas would be difficult when rushing through a text. And it is easier to rush through easy parts of a task and skip the more difficult sections.

Belief in separate knowing and belief that knowledge is a constructive process also contributed to cultural differences in study strategies. Students who scored low on selecting main ideas, testing strategies, and information processing were less likely to believe in separate knowing. To understand the implications of these results, consider the students' scores for information processing. These scores involve students' use of strategies that lead to elaboration, organization, and linking prior knowledge with new knowledge (Weinstein & Palmer, 2002). The more students believe that knowledge is constructed and believe in separate knowing, the more likely they are to use information processing strategies. Indeed, if one believes knowledge is an integrated creation of ideas knitted together, one is more likely to engage in strategies that show connections between new ideas and one's own prior knowledge. Furthermore, engaging in evaluative or critical think-

Table 5

*Summary of Regression Analyses: Epistemological Beliefs as Predictors of Study Strategies, EUROA versus BEYONDAA*

Criterion variable	Predictor variable	$R^2$	Standardized $B$ weight	$F$ change	Sig.
Select main ideas	Speed	.09	0.29	14.53	.001
High motivation	Speed	.13	0.35	21.95	.001

Variable	EUROA <i>M (SD)</i>	FIRSTAA <i>M (SD)</i>	BEYONDAA <i>M (SD)</i>
Course grade <sup>a</sup>			
Male	8.85 (3.27)	7.38 (3.30)	7.81 (3.22)
Female	10.03 (2.18)	8.44 (2.19)	8.04 (3.20)
Total	9.45 (2.81)	7.99 (2.77)	7.94 (3.19)
Reading score <sup>b</sup>			
Male	36.86 (3.34)	33.94 (5.74)	35.30 (5.23)
Female	36.32 (3.19)	34.40 (4.94)	35.02 (4.48)
Total	36.59 (3.26)	34.20 (5.28)	35.14 (4.80)

*Note.* Course grade ranged from A (12) to F (0). EUROA = Euro-Americans; FIRSTAA = first-generation Asian Americans; BEYONDAA = beyond-first-generation Asian Americans; Sig. = significance.

<sup>a</sup>EUROA was significantly different from both Asian groups.

<sup>b</sup>EUROA was significantly different from FIRSTAA.

ing would also encourage students to check consistency in logic between prior knowledge and new knowledge as well as consistency among the ideas presented.

Even more convincing evidence of the role of epistemological beliefs in learning was found in the examination of students' actual classroom performance for a business communication class. European Americans outperformed both Asian American groups in the business communication class. When epistemological beliefs, study strategies, and English as a native language were allowed to enter the equation to predict class performance, speed of learning and ability to concentrate predicted the final course grade.

Although Asian Americans are often perceived as outperforming Euro-American students, much of the past research that compared Asian American students to Euro-American students has focused on mathematics and science (Wang & Lin, 2005). When an overall math score was used as the dependent variable, Asian Americans typically outperformed Euro-American students. By contrast, when specific subtest scores were used, Asian Americans outperformed Euro-American students on calculation and routine problem solving. However, Euro-American students outperformed Asian American students on problems that were open-ended or required creativity.

It is important to keep in mind that the coursework in this study did not involve mathematics or science. Rather, the focus was on written and oral communication, group work, and critical thinking. For example, students in this study were assigned complex projects that required oral presentation and group exercises. Through these

assignments, students were required to demonstrate a proficiency in their verbal communication and business etiquette by planning, preparing, organizing, and effectively presenting various topics to multiple audiences. Specifically, this course work required creativity, cognitive flexibility, and a full array of skills.

This study provides impetus for future research in its limitations and questions left unanswered. First, this study did not specifically investigate the factor structure of epistemological beliefs or study strategies for Asian Americans. It is possible that these constructs do not manifest themselves in the same way as they do in European Americans, and this may have contributed to the somewhat lower interitem correlations (Cronbach's alpha coefficients) among some of the variables. Second, there was a significant age difference between EUROA students and BEYONDAA students. Thus, age is a potential confound in all comparisons between these two groups. This suggests that the next step is to conduct studies that carefully control for age and obtain multiple measures of epistemically related beliefs and study strategies. In addition, many questions remain unanswered. Would individual differences account for differences among cultures if the focus were on mathematics, history, computer science, engineering, or law? More importantly, if students were given instruction to enhance their study strategies and epistemically related beliefs (e.g., explicit instruction on knowledge integration, semester-long class projects, and study skills), would cultural differences decrease?

The present study supports the idea that epistemological beliefs are critical to learning and that cultural differences exist within learning environments. Furthermore, cultural stereotypes that denote one ethnic group as having the ideal or superior students should be avoided. These stereotypes could lead instructors to ignore students belonging to such groups who are struggling, yet reticent to ask for help (D. W. Sue & Sue, 2003; Wang & Lin, 2005). This stereotype could also be an important contributor to why students do not seek help from an instructor. For example, Lee (1994) writes about her ethnographic experiences with an academically struggling Asian American student:

When I suggested to Ming that he attend the tutoring sessions, Ming shook his head and said that he would not even consider attending these sessions. Ming said that it would be embarrassing to reveal his academic difficulties and that Asians did not talk about their problems. In his words: "You know, Asians don't talk about their problems—we just keep it inside—My father would kill me if I talk about stuff." Ming was referring to the Asian ethos that states that an individual's first loyalty is to his/her family and that "bad" behavior

Table 7  
*Summary of Regression Analyses: Epistemological Beliefs and Study Strategies as Predictors of Academic Performance*

Criterion variable	Predictor variable	<i>R</i> <sup>2</sup>	<i>b</i> weight	<i>F</i> change	Sig.
Final course grade	Speed	.09	0.21	18.90	.001
	Concentration	.05	0.11	10.85	.001
	Gender	.04	1.25	10.63	.001

	Native English	.07	-2.57	11.44	.001
	Study aids	.03	0.15	4.59	.05

*Note.* Sig. = significance

(i.e., disclosure of failure) on the part of the individual shames the entire family (S. Sue & Sue, 1971). (Lee, 1994, p. 421)

For all intents and purposes, the avoidance of stereotyping is important for all students. Do not assume that a student slouched in his or her desk does not care about learning. Do not assume that a student who does not raise his or her hand to ask a question really has a strong understanding of the content. Do not assume that a student who dominates a group discussion is actually a strong leader in the class. Do not assume that a student who complains that there is too much homework is just lazy. Stereotypes lead to unchecked assumptions and subsequent default instructional techniques that can shortchange students.

The epistemically related beliefs of all students must be taken into consideration for instruction, testing, and intervention. Because cultural differences play an important role in learning, including research findings on epistemological beliefs and ways of knowing may enhance the classroom curriculum. Culturally sensitive curricula may alleviate student anxieties. It may help students to reassess their personal identities and self-esteem regarding their learning traits and practices. Such an approach to all learning environments, regardless of the content area, will provide a broader and pragmatic application of diversity research among college students.

### Members of Underrepresented Groups: Reviewers for Journal Manuscripts Wanted

If you are interested in reviewing manuscripts for APA journals, the APA Publications and Communications Board would like to invite your participation. Manuscript reviewers are vital to the publications process. As a reviewer, you would gain valuable experience in publishing. The P&C Board is particularly interested in encouraging members of underrepresented groups to participate more in this process.

If you are interested in reviewing manuscripts, please write to the address below. Please note the following important points:

- To be selected as a reviewer, you must have published articles in peer-reviewed journals. The experience of publishing provides a reviewer with the basis for preparing a thorough, objective review.
- To be selected, it is critical to be a regular reader of the five to six empirical journals that are most central to the area or journal for which you would like to review. Current knowledge of recently published research provides a reviewer with the knowledge base to evaluate a new submission within the context of existing research.
- To select the appropriate reviewers for each manuscript, the editor needs detailed information. Please include with your letter your vita. In the letter, please identify which APA journal(s) you are interested in, and describe your area of expertise. Be as specific as possible. For example, “social psychology” is not sufficient—you would need to specify “social cognition” or “attitude change” as well.
- Reviewing a manuscript takes time (1–4 hours per manuscript reviewed). If you are selected to review a manuscript, be prepared to invest the necessary time to evaluate the manuscript thoroughly.

Write to Journals Office, American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242.

# Heuristics and Biases as Measures of Critical Thinking: Associations with Cognitive Ability and Thinking Dispositions

Richard F. West  
James Madison University

Maggie E. Toplak  
York University

Keith E. Stanovich  
University of Toronto

In this article, the authors argue that there are a range of effects usually studied within cognitive psychology that are legitimately thought of as aspects of critical thinking: the cognitive biases studied in the heuristics and biases literature. In a study of 793 student participants, the authors found that the ability to avoid these biases was moderately correlated with a more traditional laboratory measure of critical thinking—the ability to reason logically when logic conflicts with prior belief. The correlation between these two classes of critical thinking skills was not due to a joint connection with general cognitive ability because it remained statistically significant after the variance due to cognitive ability was partialled out. Measures of thinking dispositions (actively open-minded thinking and need for cognition) predicted unique variance in both classes of critical thinking skills after general cognitive ability had been controlled.

**Keywords:** critical thinking, heuristics and biases, intelligence, thinking dispositions

In the critical thinking literature, the ability to evaluate evidence and arguments independently of one's prior beliefs and opinions is a skill that is strongly emphasized (Baron, 1991, 2000; Ennis, 1987, 1996; Perkins, 1995; Sternberg, 1997, 2001, 2003). Virtually all measures of critical thinking try to assess the ability to avoid reasoning that is too biased by prior opinion and prior belief (e.g., Ennis, Millman, & Tomko, 1985; Facione, 1992; Norris & Ennis, 1989; Watson & Glaser, 1980).

The Watson-Glaser Critical Thinking Assessment (WGCTA; Watson & Glaser, 1980) is widely used and is representative of the discourse-logic-based critical thinking measures that have played a prominent role in critical thinking assessment. The WGCTA is an 80-item multiple choice test that comprises five subsets of items (Inference, Recognition of Assumptions, Deduction, Interpretation, and Evaluation of Arguments). Each test item generally consists of a series of statements about which the validity of various conclusions must be judged. Four of the WGCTA's five subscales emphasize the propositional logic of necessity rather than sufficiency. The test's authors acknowledge that strong opinions and beliefs have the potential to adversely influence people's ability to think critically, and the WGCTA includes both neutral

items and items on issues that are assumed likely to provoke a pressure to be biased. Thus, four of the five subscales admonish the test-taker to regard even factually questionable statements as correct for the purposes of the test (e.g., "For the purposes of this test, consider the statements in each exercise as true without exception"; "Try not to let your prejudices influence your judgment—just stick to the given statements [premises] and judge each conclusion as to whether it necessarily follows from the premises" [Harcourt Assessment, 2006, p. 4]). This emphasis on the importance of avoiding unbiased reasoning is also a common feature of the other discourse-logic-based critical thinking measures (e.g., Cornell Critical Thinking Tests, Ennis et al., 1985; California Critical Thinking Skills Test, Facione, 1992), and shares a common motivational underpinning with a number of tasks examined by cognitive scientists. Historically, Piaget's (1972) conceptualization of formal operational thought places such mechanisms of decontextualization—freeing from irrelevant context—in positions of paramount importance, because according to his view, "one of the essential characteristics of formal thought appears to us to be the independence of its form from reality content" (p. 10).

In the laboratory, the ability to reason in an unbiased manner has been operationalized with a few well-known paradigms. The belief bias syllogism task, one of the most thoroughly explored of these paradigms, shares a number of important features with discourse-logic-based critical thinking measures. This paradigm assesses the tendency for judgments of logical validity to be contaminated by prior knowledge of the world—for example, when the validity of a syllogism and the facts expressed in the conclusion of the syllogism conflict (e.g., "All flowers have petals; roses have petals; therefore, roses are flowers"—which is invalid under necessity). The inability to decouple prior knowledge from reasoning processes has been termed the *belief bias effect* (Evans, Barston, & Pollard, 1983). It has been the subject of extensive study in the cognitive science literature, and several formal models of how belief bias operates to disrupt syllogis-

tic reasoning have been proposed (De Neys, 2006; Evans & Curtis-Holmes, 2005; Evans & Feeney, 2004; Garnham & Oakhill, 2005; Klauer, Musch, & Naumer, 2000).

Belief bias has also been revealed in paradigms in which participants must evaluate the quality of empirical evidence in a manner not contaminated by their prior opinion on the issue in question. In several studies, Klaczynski (1997) and colleagues (Klaczynski & Gordon, 1996; Klaczynski & Lavalley, 2005; Klaczynski & Robinson, 2000) presented participants with flawed hypothetical experiments that led to conclusions that were either consistent or inconsistent with prior positions and opinions. Participants then critiqued the flaws in the experiments (which were most often badly flawed). Participants found many more flaws when the experiment's conclusions were inconsistent with their prior opinions than when the experiment's conclusions were consistent with their prior opinions and beliefs.

It is, of course, important to show that the ability to reason independently of prior opinion is not entirely coexistent with general cognitive ability (intelligence), and there has been some preliminary evidence indicating that this is in fact the case. The tendency toward biased reasoning in the experiment evaluation paradigms (as well as related paradigms) shows considerable dissociation from cognitive ability (Kardash & Scholes, 1996; Klaczynski & Gordon, 1996; Klaczynski & Lavalley, 2005; Klaczynski & Robinson, 2000; Macpherson & Stanovich, 2007). Belief bias in syllogistic reasoning has shown a significant correlation with cognitive ability, but it is modest in size and does not exhaust the reliable variance in the magnitude of the bias displayed. We know the latter because various thinking dispositions (actively open-minded thinking, need for cognition) have been found to predict belief bias after the variance in cognitive ability has been partialled out (Kokis, Macpherson, Toplak, West, & Stanovich, 2002; Sá, West, & Stanovich, 1999; Stanovich & West, 1998).

The ability to reason independently of prior belief is only one component of critical thinking. Many theorists view critical thinking as a subspecies of rational thinking or at least as closely related to rational thinking (Kuhn, 2005; Moshman, 2004, 2005, in press; Reyna, 2004; Siegel, 1988, 1997). Cognitive scientists recognize two types of rationality: instrumental and epistemic. To think rationally means adopting appropriate goals, taking the appropriate action given one's goals and beliefs, and holding beliefs about the world that are commensurate with available evidence. These characteristics of rational thinking are precisely the features that a number of leading critical thinking theorists have highlighted in recent descriptions of critical thinking. Thus, Ennis (1996) describes critical thinking as "a process, the goal of which is to make reasonable decisions about what to believe and what to do" (p. xvii), Halpern (2008) states that "critical thinking is the use of those cognitive skills or strategies that increase the probability of desirable outcomes" (p. 3), and Facione (2007) emphasizes the importance of making purposeful, reflective judgments "about what to believe or what to do—precisely the kind of judgment which is the focus of critical thinking" (p.13).

If one accepts the theoretical linkage between critical thinking and rational thought, then there may well be other aspects of critical thought beyond the avoidance of egocentric processing that has been emphasized in previous work in critical thinking. However, we would also want any new domain of critical thinking to at least partially dissociate from measures of cognitive ability (as does the avoidance of belief bias). In this study, we examined one

candidate class of biases that qualify as indices of critical/rational thought and that may well dissociate from cognitive ability because tests of the latter do not assess it directly.

A prime candidate for a cognitive domain not assessed by tests of intelligence or tests of critical thinking is found in the panoply of effects studied in the heuristics and biases literature, which has a 30-year history in cognitive psychology (Evans, 1989, 2007; Evans & Over, 1996; Gilovich, Griffin, & Kahneman, 2002; Kahneman, 2003; Kahneman & Tversky, 1973, 1996, 2000; Over, 2004; Tversky & Kahneman, 1974, 1983, 1986). Many of the heuristics and biases studied relate to important aspects of rational and critical thought: causal reasoning, probabilistic reasoning, hypothetical thought, theory justification, assessment of the covariation of events, scientific reasoning, disjunctive reasoning, the tendency to think statistically, and the tendency to think of alternative explanations. These areas are legitimately classified as part of critical thinking. Research in the field of cognitive psychology has shown that these thinking characteristics can be measured and that they relate to important real-world decisions in domains such as personal finance, employment, health, and public policy (Baron, Bazerman, & Shonk, 2006; Hastie & Dawes, 2001; Hilton, 2003; Kahneman & Tversky, 2000; Lichtenstein & Slovic, 2006; Myers, 2002; Reyna & Farley, 2006; Reyna & Lloyd, 2006; Sunstein, 2002, 2005).

In short, on theoretical grounds, the traditional heuristics and biases studied by cognitive psychologists should be considered to be part of a broadened concept of critical thinking. We wish here to introduce theorists to this class of thinking skills because they are largely untapped by currently used critical thinking tests and to provide a preliminary indication of their likely empirical relationships to related constructs. In this investigation, we began some of the empirical groundwork for a theoretical integration of the heuristics and biases framework with more traditional approaches to critical thinking. We examined their relationship to an empirical marker of classic definitions of critical thinking (belief bias in logical reasoning) as well as their relationship to cognitive ability and thinking dispositions.

Although a heuristic process can result in behavior that is appropriate for a given purpose (e.g., unreflectively looking both ways before crossing a street), the set of tasks that we explored highlight important situations in which heuristics and biases are negatively associated with good critical thinking, and result in poor judgments and decisions about what to believe and what to do. Thus, in this article, we posit that the override of heuristics and the avoidance of biases are related to critical thinking.

We should emphasize that the large collection of skills and tasks from the heuristics and biases literature that we examined are not represented on traditional critical thinking tests like the WGCTA. For example, the WGCTA and similar genre of critical thinking tests do not assess the use of base rates in probabilistic reasoning; they do not tap knowledge of the law of large numbers or the ability of people to make regressive probabilistic predictions. They do not assess the gambler's fallacy, nor, in general, do they assess covariation detection, denominator neglect, or Bayesian probabilistic updating. In addition, they do not assess a critical aspect of rationality, *descriptive invariance*, that is the property that causes framing effects when violated (for reviews of the large body of literature on each of these effects, see Gilovich et al., 2002; Nickerson, 2004; Reyna, Lloyd, & Brainerd, 2003; Stanovich, 1999, 2004, 2008b). All of these effects and biases were examined in the present study.

In addition to examining the relationship between these varied measures of the ability to avoid heuristics and cognitive biases, we used the syllogistic reasoning task as an index of the type of discourse-logic-based reasoning skills that are assessed with traditional critical thinking tests like the WGCTA—the critical ability to reason logically when logic conflicts with prior belief. We examined whether cognitive ability was coextensive with variation on these two classes of critical thinking skills and whether cognitive ability mediated any connection between the two critical thinking skills. Additionally, we examined two thinking dispositions that have been found to be independent predictors of belief bias (need for cognition and actively open-minded thinking) in order to ascertain whether they were likewise independent predictors of the ability to avoid cognitive biases.

## Method

### *Participants and Procedure*

The participants were 793 undergraduate students (264 men and 529 women) recruited through an introductory psychology subject pool at a medium-sized state university. Their mean age was 19.0 years ( $SD = 2.1$ ). The majority of these students were freshmen (486 students) or sophomores (213 students), and a minority were juniors (65 students) and seniors (27 students). The year in college was missing for 2 participants. Almost 89% of them identified themselves as White (704 students), and a minority identified themselves as African American (20 students), Asian American (42 students), or “other” race/ethnicity (27 students).

Participants completed the battery of tasks during a single, 2-hr session. After completing the informed consent and demographic information sheet, participants completed, in order, the thinking disposition items, the syllogistic reasoning task, and the heuristics and biases tasks.

### *Tasks and Variables*

#### *Syllogistic Reasoning Problems with Belief Bias*

Twelve syllogistic reasoning problems, largely drawn from Markovits and Nantel (1989), were completed by the participants. Each problem was worded such that the validity judgment was in conflict with the believability of the conclusion. There were two types of these so-called inconsistent syllogisms. One type of inconsistent syllogism had a believable conclusion but an invalid format (e.g., “All flowers have petals; roses have petals; therefore, roses are flowers”—which is invalid). The other type had an unbelievable conclusions in a logically valid format (e.g., “All things with four legs are dangerous; poodles are not dangerous; therefore, poodles do not have four legs”—which is valid). Therefore, the believability of the content was inconsistent with the logical format of the syllogism in both types. Problems of this type have typically been thought to mirror the critical thinking skill of being able to put aside one’s prior knowledge and reason from new premises. After each item, the participants indicated their responses by selecting one of the two alternatives: (a) Conclusion follows logically from premises, or (b) Conclusion does not follow logically from premises. Scores on the inconsistent syllogisms ranged from 0 to 12 ( $M = 6.9$ ,  $SD = 3.0$ ).

#### *Heuristics and Biases Tasks*

*Causal Base Rate 1: Volvo problem.* In this problem, adapted from Fong, Krantz, and Nisbett (1986), a couple are deciding to

buy one of two otherwise equal cars. The *Consumer Reports* survey, statistics on repair records, and polls of experts favor the Volvo over the Saab. However, a friend reports experiencing a severe mechanical problem with the Volvo he owns. The participants were asked to provide advice to the couple. Preference for the Volvo indicates a tendency to rely on the large-sample information in spite of salient personal testimony. A preference for the Saab indicates reliance on the personal testimony over the opinion of experts and the large-sample information. Any degree of preference for the Volvo was scored as 1, and any degree of preference for the Saab was scored as 0.

*Causal Base Rate 2: Superintendent problem.* This is a slightly edited and revised version of a problem in Fong et al. (1986) that was analogous to the Volvo problem and was scored similarly. In this scenario, the superintendent of schools is urging the school board to make a curriculum shift. The superintendent must trade off the evidence of empirical studies conducted on a large sample of school districts that points in one direction versus the testimony of a school board member with a personal anecdote that points in the other direction.

*Noncausal base rate problem.* Base rates that have a causal relationship to the criterion behavior (Ajzen, 1977; Bar-Hillel, 1990; Tversky & Kahneman, 1979) are often distinguished from noncausal base rate problems—those involving base rates with no obvious causal relationship to the criterion behavior. In the previous two problems the statistical base rate information was causal (the *Consumer Reports* survey and the empirical studies of the school districts). In contrast, this problem is an adaptation of a noncausal base rate problem that has been much studied (Casscells, Schoenberger, & Graboys, 1978; Sloman, Over, Slovak, & Stibel, 2003; Stanovich & West, 1999, 2000). The problem was worded as follows:

It is known that 1 dollar out of every 10,000 is counterfeit. Imagine a money-changing machine that rejects real dollar bills 5 out of every 100 times it changes money. However, it always rejects bills when they are counterfeit. If this machine rejects your dollar bill, what is the probability (expressed as a percentage ranging from 0% to 100%) that your bill is counterfeit? Choose the best answer.

The problem was followed by the choices: (a) Less than 1%, (b) About 5%, (c) About 50%, (d) About 95%, and (e) More than 95%. Alternative a is the correct response and was scored as 1 (other responses were scored as 0).

*Law of large numbers: Hospital problem.* This problem is a classic and much-cited problem studied by Tversky and Kahneman (1974). It is used to explore participants’ understanding that, other things being equal, a larger sample size more accurately estimates a population value.

*Regression to the mean.* Drawn from Lehman, Lempert, and Nisbett (1988), this is a multiple-choice problem involving baseball batting averages, and only one of the alternatives shows some recognition of the possibility of regression effects and was scored as 1. Other options were scored as 0.

*Gambler’s Fallacy 1.* In the first gambler’s fallacy problem—the slot machine problem—the participant read the following:

When playing slot machines, people win something about 1 in every 10 times. Lori, however, has just won on her first three plays. What are her chances of winning the next time she plays? Choose the best answer.

The problem was followed by the choices: (a) She has better than 1 chance in 10 of winning on her next play, (b) She has less

than 1 chance in 10 of winning on her next play, (c) She has a 1 chance in 10 that she will win on her next play. The correct response of c was scored as 1, while any other response incorrect and scored as 0.

*Gambler's Fallacy 2.* This problem is similar to the last and involves coin tosses.

*Conjunction problem.* This problem is based on Tversky and Kahneman's (1983) much-studied Linda problem, one of the most studied problems in the heuristics and biases literature. Conjunction problems assess whether people appreciate that the probability of Event A and Event B both occurring must be lower than the probability of either A or B alone occurring.

*Covariation detection.* This problem appeared as follows:

A doctor had been working on a cure for a mysterious disease. Finally, he created a drug that he thought would cure people of the disease. Before he could begin to use it regularly, he had to test the drug. He selected 400 people at random who had the disease. Of the 400, he randomly assigned 300 to the treatment group and gave them the drug to see what happened. He randomly assigned 100 people to the no-treatment group and gave them a placebo (a sugar pill manufactured to look like the treatment drug) to see what happened. The table below indicates the outcome (Figure 1):

Drug condition	Group	
	Cured	Not cured
Received	200	100
Did not receive	75	25

Does the drug work?

Figure 1.

Participants were asked to choose the statement that best summarized the results shown in the table from among the following statements: (a) The evidence indicates that the drug was effective, (b) The evidence is inconclusive, or (c) The evidence indicates that the drug was not effective. The correct response, c, was scored as 1 (the other responses were scored as 0).

*Methodological reasoning.* Adapted from Lehman et al. (1988), this multiple-choice problem has only one alternative that indicates the ability to reason methodologically about confounded variables in everyday life. It was scored as 1 and the other responses as 0.

*Bayesian Reasoning 1.* This problem was the David Maxwell problem adapted from Beyth-Marom and Fischhoff (1983) and studied by Stanovich and West (1998). It is used to assess Bayesian belief updating.

*Bayesian Reasoning 2.* This problem was the Mark Smith problem adapted from Beyth-Marom and Fischhoff (1983) and studied by Stanovich and West (1998). It is used to assess Bayesian belief updating.

*Four card selection task.* Originally used by Wason (1966), the selection task has been studied extensively in the reasoning literature (e.g., Evans, Newstead, & Byrne, 1993; Evans & Over, 1996; Johnson-Laird, 1999). The problem involves reasoning about whether an "if-P-then-Q" type of rule can be falsified. Because the rule is in the form of an if-P-then-Q rule, the partic-

ipant must turn over the two cards that could potentially falsify the rule—the P card and the not-Q card (in this case, the Baltimore and train cards), which is the correct answer and was scored as 1. Very few participants give this completely correct response. Thus, we scored the task leniently by including as correct an alternative task construal championed by Margolis (1987). He has argued that turning the P card only is an appropriate response if the participant has adopted a so-called "open" reading of the rule—one in which the cards represent classes rather than individual exemplars. Therefore, the selection of the P card only was considered a correct answer and also scored as 1. All other selections were scored as 0.

*Framing problem.* The much-researched disease framing problem was originally studied by Tversky and Kahneman (1981). This problem is presented in two parts: positive and negative framing. Descriptive invariance is correct and was scored as 1. Violation of description invariance was scored as 0.

*Probabilistic reasoning: Denominator neglect.* This probabilistic reasoning task is a marble game that was modeled on a task introduced by Kirkpatrick and Epstein (1992; see also Denes-Raj & Epstein, 1994; Reyna, 1991; Reyna & Brainerd, 1994, 2007). The problem read as follows:

Assume that you are presented with two trays of black and white marbles: a large tray that contains 100 marbles and a small tray that contains 10 marbles. The marbles are spread in a single layer on each tray. You must draw out 1 marble (without peeking, of course) from either tray. If you draw a black marble, you win \$2. Consider a condition in which the small tray contains 1 black marble and 9 white marbles, and the large tray contains 8 black marbles and 92 white marbles. [A drawing of two trays with their corresponding numbers of marbles arranged neatly in 10-marbles-rows appeared above the latter sentence.] From which tray would you prefer to select a marble in a real situation?

The correct response is to select the small tray and was scored as 1.

*Disjunctive reasoning.* This problem was drawn from Levesque (1986, 1989) and is a variant on ones used by Toplak and Stanovich (2002). The problem was presented as follows:

There are 3 blocks in a stack, where each of the blocks is either new or old. The top block is new, and the bottom one is old. The middle block is either new or old. Is there a new block directly on top of an old block?

The text of the problem was accompanied by a graphic that displayed three blocks with their corresponding descriptions. The top block was labelled "new" the middle block was labelled "new or old", and the bottom block was labelled "old."

Participants were presented with the following alternatives: (a) Yes, (b) No, and (c) Cannot be determined. In order to solve this problem, one needs to consider the disjuncts of the middle box. That is, if the middle box is new, then the answer is "yes" because it would be on top of the bottom box, which is old. If the middle box is old, then the answer is still "yes" because the top box would now be on top of the middle box, which is old. The correct solution is thus "yes" and was scored as 1, and other responses were scored as 0.

*Heuristics and biases composite score.* For the purposes of several of the analyses reported below, we summed the scores on the 16 heuristics and biases tasks to form a composite score ( $M = 7.7$ ,  $SD = 2.6$ , range = 1–15). By forming a composite score, we do not mean to imply that these heuristics and biases tasks form a unidimensional construct. Previous intercorrelations of smaller sets of these tasks than those used here have shown that they are

only modestly correlated (Bruine de Bruin, Parker, & Fischhoff, 2007; Klaczynski, 2001; Parker & Fischhoff, 2005; Stanovich & West, 1998, 2000). The rational thinking tendencies measured by these heuristics and biases tasks are probably multifarious (Parker & Fischhoff, 2005; Reyna et al., 2003; Stanovich 2008a, 2008b; Toplak, Liu, Macpherson, Toneatto, & Stanovich, 2007). Finally, each task, from a psychometric point of view, represents only a single item. Thus, only modest reliability for the composite score is expected, and this was the case. The split-half reliability was .52, and Cronbach's alpha was .53.

### Cognitive Ability

Students were asked to indicate their verbal, mathematical, and total SAT scores on the demographics form. The mean reported verbal SAT score of the students was 584 ( $SD = 70$ ), the mean reported mathematical SAT score was 590 ( $SD = 68$ ), and mean total SAT score was 1,173 ( $SD = 102$ ). These self-reported scores closely matched the averages for this institution at the time of testing (582, 587, and 1,169, respectively). Several studies have indicated that the correlation between self-reported SAT scores and verified SAT scores is in the range of .80—.90 (Cassady, 2001; Kuncel, Crede, & Thomas, 2005) as is the correlation between self-reported grade point average (GPA) and verified GPA (Higgins, Peterson, Pihl, & Lee, 2007). An indication of the validity of the self-reported scores is that they correlated with a third variable to the same extent as verified scores. Stanovich and West (1998) found that the correlation between scores on a vocabulary test and self-reported SAT total scores (.49) was quite similar to the .51 correlation between the vocabulary test scores and verified total SAT scores in a previous investigation using the same vocabulary measure (West & Stanovich, 1991). The total SAT score is used as an index of cognitive ability in the analyses reported here because it loads highly on psychometric general intelligence as measured by a variety of indicators (Frey & Det-

terman, 2004; Unsworth & Engle, 2007). The total SAT score will be used in the analyses reported here.

### Thinking Dispositions

Two thinking dispositions were measured—actively open-minded thinking (Stanovich & West, 1997, 2007) and need for cognition (Cacioppo, Petty, Feinstein, & Jarvis, 1996). Items from the two scales were intermixed. We used the 41-item Actively Open-Minded Thinking (AOT) Scale (Stanovich and West, 2007). All items were scored such that higher scores represented a greater tendency toward open-minded thinking. Examples of items are “People should always take into consideration evidence that goes against their beliefs”; “Certain beliefs are just too important to abandon, no matter how good a case can be made against them” (reverse scored); and “No one can talk me out of something I know is right” (reverse scored). The responses for each item in the questionnaire were *strongly agree* (6), *moderately agree* (5), *slightly agree* (4), *slightly disagree* (3), *moderately disagree* (2), and *strongly disagree* (1). Higher scores on the scale indicate cognitive flexibility and lower scores indicate cognitive rigidity and resistance to belief change. The score on the scale was obtained by summing the 41 responses to the items ( $M = 170.5$ ,  $SD = 18.3$ ). The split-half reliability (Spearman-Brown corrected) of the scale was .76, and Cronbach's alpha was .84. The total score on the AOT scale was standardized, and the  $z$  score was used in statistical analyses.

The 18-item Need for Cognition Scale (Cacioppo et al., 1996) was used in this study. Sample items include “The notion of thinking abstractly is appealing to me,” and “I would prefer a task that is intellectual, difficult, and important to one that is somewhat important but does not require much thought.” The response format for each item in the questionnaire was the same as that used for the AOT. The mean score was 69.0 ( $SD = 12.2$ ). The split-half reliability (Spearman-Brown corrected) of the Need for Cognition Scale was .81, and Cronbach's alpha was .88. The total score on the scale was standardized, and the  $z$  score was used in statistical analyses.

Table 1

*Heuristics and Biases Tasks: Percentage Correct, Correlations, and Partial Correlations, With SAT Total Covaried*

Disjunctive reasoning	37.7	.205***	.085*	.172***	.093**

Note.  $N = 793$ . SAT = SAT total.

<sup>a</sup> Thinking disposition composite. <sup>b</sup> Belief bias syllogisms.

\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

A composite thinking dispositions score was also constructed. The  $z$  scores for the AOT and Need for Cognition scales were summed to create a composite score of these two measures. The reliability of the Composite Thinking Dispositions Scale was .88 (Cronbach's alpha).

### Results

Table 1 displays the percentage of participants who responded correctly on each of the heuristics and biases tasks. There is considerable variation in task difficulty. Consistent with the extensive literature on the difficulty of the four card selection task (e.g., Evans, 2006; Evans et al., 1993), this task was solved by less than 20% of the participants (the lowest solution rate of all the tasks). The easiest task was the second gambler's fallacy problem, which was answered correctly by almost 80% of the participants. More important is the fact that each of these tasks was answered incorrectly by at least substantial minorities. This is significant because, collectively, these tasks assess whether people adhere to some of the most fundamental strictures of rational thought (see Evans & Over, 1996; Gilovich et al., 2002; Kahneman & Tversky, 1996, 2000; Over, 2004; Samuels & Stich, 2004; Stanovich, 1999, 2004, 2008b; Stein, 1996). These results converge with those reported in a small body of work indicating that the susceptibility to these biases varies considerably (Bruine de Bruin et al., 2007; Klaczynski, 2001; Parker & Fischhoff, 2005; Stanovich & West, 1998, 2000, 2008). What predicts this variation in the susceptibility to these biases, and how does this variation relate to that in another foundational critical thinking skill—reasoning independently of prior belief? The next several analyses address these questions in various ways.

The second column in Table 1 lists the zero-order correlations between each of the 16 heuristics and biases tasks and the SAT total. Twelve of the 16 correlations in this column were significant. The four nonsignificant correlations were found for the law of large numbers, conjunction problem, covariation detection, and methodological reasoning problems. The third column lists the zero-order correlations between the heuristics and biases tasks and the thinking dispositions composite. Eleven of these 16 correlations were significant. Although the correlations between the reasoning tasks and thinking dispositions were more modest than those involving SAT, most once again reached a level of statistical significance. The five nonsignificant correlations were found for the law of large numbers, regression to the mean, the conjunction problem, covariation detection, and methodological reasoning problems. The fourth column lists the zero-order correlations between the heuristics and biases tasks and the belief bias syllogisms. Thirteen of these 16 correlations were significant. The three nonsignificant correlations were found for the law of large numbers, the conjunction problem, and methodological reasoning tasks. The final column displays the partial correlations between the heuristics and biases tasks and belief bias syllogisms after SAT was statistically covaried. Even after SAT was statistically partialled, 11 of the 16 correlations remained significant. Across the four columns displaying correlational data, only 3 of the 16 heuristics and biases tasks (law of large numbers, conjunction problem, and methodological reasoning) failed to demonstrate any reliable relationships with the other major measures.

Table 2 presents the zero-order correlations among the major variables in the study.<sup>1</sup> Because of the large sample size in the

Table 2

*Correlations Between Cognitive Ability, Thinking Dispositions, Heuristics and Biases Composite Score, and Syllogistic Reasoning With Belief Bias*

Variable	1	2	3	4	5	6
1. SAT total score	—					
2. AOT $z$ score	.205	—				
3. Need for Cognition $z$ score	.239	.401	—

5. Heuristics and biases composite score	.390	.213	.247	.275	—	
6. Belief bias syllogisms	.441	.191	.225	.248	.437	—

*Note.* Values greater than  $r = .117$  significant at  $p < .001$ . AOT = Actively Open-Minded Scale.

study, all correlations were significant at the .001 level. The two components of critical thinking—avoidance of thinking biases and syllogistic reasoning independent of prior belief—displayed a moderate correlation with each other (.437). Both variables were moderately correlated with cognitive ability (.390 and .441, respectively) and modestly correlated with the composite thinking dispositions measure (.275 and .248, respectively). Because the association between the two thinking dispositions, the AOT and the Need for Cognition  $z$  scores, was relatively moderate ( $r = .401$ ,  $p < .001$ ), analyses paralleling those subsequently reported for the thinking disposition composite were also conducted on the AOT and on the Need for Cognition  $z$  scores separately.<sup>2</sup>

Previous research (Kokis et al., 2002; Stanovich & West, 1998) has found that variation in thinking dispositions related to cogni-

<sup>1</sup> One caveat concerning the associations that we observed in these studies relates to the restriction of range in our sample. Certainly, it is true that individuals with average and above-average cognitive ability are over-represented in samples composed entirely of university students. Nevertheless, the actual range in cognitive ability found among college students in the United States is quite large. In the past 30 years, the percentage of 25- to 29-years-olds in the United States who have attended college has increased by 50%. By 2002, 58% of these young adults had completed at least 1 or more years of college, and 29% had received at least a bachelor's degree (U.S. Department of Health and Human Services, 2003). However, the restriction of range in cognitive ability was somewhat greater in our sample, because our participants attended a moderately selective state university. The SAT total means of our sample were roughly .74 of a standard deviation above the national mean (College Board, 2006). The standard deviation of the distribution of scores in our sample was roughly .50 of the standard deviation in the nationally representative sample.

<sup>2</sup> Separate analyses involving the AOT and need for cognition thinking dispositions were also conducted in parallel to all of the analyses in this article in which the thinking dispositions composite score was used. Across the analyses, the pattern of findings for the two component dispositions closely matched those found for the composite measure. Both the AOT and need for cognition were individually significant predictors of performance in all of the regression analyses presented in Table 3, and both AOT and need for cognition accounted for comparable unique and common variance in the commonality analyses shown in Table 4. In each case, however, the thinking disposition composite measure accounted for a larger proportion of variance on the criterion variables.

tive flexibility predicts the avoidance of belief bias in reasoning after variation in cognitive ability has been controlled. The first regression analysis in Table 3 represents a replication of this finding. When entered first as a predictor of performance on the belief bias syllogisms, SAT total predicted 19.4% of the variance and, when entered second, the thinking dispositions composite predicted a statistically significant 1.9% of variance ( $p < .001$ ). The simultaneous regression of these two variables on belief bias syllogism performance indicated that cognitive ability was a more potent unique predictor (15.1% unique variance). A comparison of the simultaneous beta weights indicated the same thing.

The next regression analysis in Table 3 indicated that the thinking dispositions composite was likewise a unique predictor of the heuristics and biases composite score. When entered first as a predictor, SAT total predicted 15.2% of the variance and, when entered second, the thinking dispositions composite predicted a statistically significant 3.2% of variance ( $p < .001$ ). The simultaneous regression of these two variables on heuristics and biases performance indicated that cognitive ability was a more potent unique predictor (10.9% unique variance). A comparison of the simultaneous beta weights converged with this conclusion, although the variables were more balanced predictors than was the case in the analysis of syllogistic reasoning.

As shown in Table 2, the two components of critical thinking displayed a moderate correlation with each other (.437). The next analysis explored whether the link between the two was

entirely mediated by cognitive ability. The criterion variable in this analysis was the heuristics and biases composite score. When entered first as a predictor, SAT total predicted 15.2% of the variance and, when entered second, performance on the belief bias syllogisms predicted a substantial 8.7% of variance ( $p < .001$ ). The simultaneous regression of these two variables on the heuristics and biases score indicates that syllogistic reasoning performance was a more potent unique predictor than SAT total score (8.7% versus 4.8% unique variance). A comparison of the simultaneous beta weights provides a redundant way of comparing the potency of the two predictors.

The last regression in Table 3 examined whether the variance overlap between the susceptibility to various cognitive biases and the ability to reason independently of prior belief remained when the variance due to both cognitive ability and thinking dispositions was controlled. When entered first as a predictor of the heuristics and biases composite, SAT total predicted 15.2% of the variance. When entered second, the thinking dispositions composite predicted an additional 3.2% of variance ( $p < .001$ ). Finally, when entered last, performance on the belief bias syllogisms accounted for a substantial 7.4% additional variance. The simultaneous regression of these three variables on the heuristics and biases score indicated that syllogistic reasoning performance was a more potent unique predictor than either SAT total score or the thinking dispositions composite score (7.4% vs. 3.8% and 1.9% unique variance, respectively). A

Note. All  $F$  values in this analysis are significant at the  $p < .001$  level.

comparison of the simultaneous beta weights provides a redundant way of comparing the potency of the three predictors.

As an additional way to reveal the overlap in the variables as predictors of susceptibility to the cognitive biases, we conducted a commonality analysis (see Pedhazur, 1997) in which the variance explained by each variable was partitioned into a portion unique to that variable and portions shared with every possible combination of variables. The results of the commonality analysis are presented in Table 4. The first row indicates the unique variance in the heuristics and biases composite score explained by each of the predictors. The next row displays the explained variance in heuristics and biases scores that was common to SAT and thinking dispositions (.010). The third row displays the explained variance in heuristics and biases scores that was common to SAT and the belief bias syllogisms (.071). The fourth row displays the explained variance in heuristics and biases scores that was common to thinking dispositions and belief bias syllogisms (.013). The fifth row indicates that the explained variance in heuristics and biases scores that was common to all three predictors is .033. All of the variance components added together (.038 + .019 + .074 + .010 + .071 + .013 + .033) summed to the total variance explained in heuristics and biases scores by the three predictors (.258).

The unique variances explained here recapitulates those derived from the regression analyses. The commonality analysis reveals that the primary reason that SAT was not a more potent unique predictor was because of its overlap with variance explained by syllogistic reasoning performance (.071). Secondarily, the unique variance explained by cognitive ability (.038) was roughly similar to that in common to all three variables (.033). In contrast, syllogistic reasoning was more separable from other predictors. The proportion of unique variance that it accounted for was 2–3 times as large as that of the other two predictors, and it was the only indicator in which the amount of unique variance explained (.074) was larger than the explained variance held in common by all three predictors (.033).<sup>3</sup>

Table 4

Common 1 & 3 <sup>c</sup>	.071	—	.071
Common 2 & 3 <sup>d</sup>	—	.013	.013
Common 1 & 2 & 3 <sup>e</sup>	.033	.033	.033
Total unique variance + common variance	.152	.075	.191

*Note.* Unique variance = explained variance in heuristics and biases composite scores that is unique to that variable.

<sup>a</sup> Thinking disposition composite. <sup>b</sup> Common 1 & 2 = explained variance that was common to Variables 1 and 2. <sup>c</sup> Common 1 & 3 = explained variance that was common to Variables 1 and 3. <sup>d</sup> Common 2 & 3 = explained variance that was common to Variables 2 and 3. <sup>e</sup> Common 1 & 2 & 3 = explained variance that was common to all three variables.

## Discussion

The cognitive biases tapped by our heuristics and biases tasks are not typically assessed by measures of critical thinking. Yet there are theoretical reasons to believe that they should be. To perform well on these heuristics and biases tasks, one needs both declarative knowledge and the proper mental strategies and metastrategies (Stanovich, 2008a, 2008b). The heuristic response must be inhibited and replaced with a more normatively appropriate response. The inhibition process depends not only on cognitive capacity but also on the metacognitive sensitivity (i.e., reflectivity; see Stanovich, 2008b) to begin the process of response suppression. Once the heuristic response is inhibited, the knowledge to make the right substitute response must be present. Declarative knowledge of probability, causal reasoning, scientific thinking, and logic comes in to play at this step.

Several cognitive theorists have analyzed critical thinking in terms of rational thinking concepts and the philosophy of rational thought (e.g., Kuhn, 2005; Moshman, 2004, in press; Siegel, 1997). For example, discussions of critical thinking often concern the thought

<sup>3</sup> Structural equation modeling analyses provided additional evidence consistent with the pattern of findings reported in Table 3 and Table 4. Four different models were evaluated for relative fit. Model 1, which is most consistent with results displayed in the regression (Table 3) and commonality (Table 4) analyses, posited four separate latent constructs, with those of cognitive ability, thinking dispositions, and belief bias syllogistic reasoning simultaneously predicting the heuristics/biases endogenous construct. Three indicators were used for cognitive ability: total SAT score, high school grade point average (GPA), and college GPA (either high school or college GPA was missing for 78 participants). Two indicators were used for thinking dispositions: Need for Cognition Scale and AOT *z* scores. We created two item parcels each as separate indicators for the belief bias syllogism and heuristics/biases latent constructs by including odd-numbered and even-numbered items in each item parcel. This resulted in two indicators for both the belief bias syllogistic reasoning and the heuristics/biases composite.

Three additional models were tested to explore how well combining the latent constructs in various ways could account for the data. The following combinations were explored: when cognitive ability and thinking dispositions were treated as one of two exogenous constructs (Model 2); when cognitive ability and syllogistic reasoning were treated as one of two exogenous constructs (Model 3); and when cognitive ability, thinking dispositions, and syllogistic reasoning were treated as the one and only exogenous construct (Model 4). The heuristics and biases composite was the endogenous construct in each model. Model 1 generated  $\chi^2(21, N = 715) = 99.2, p = .0001$ ; confidence fit index (CFI) = .95; Tucker-Lewis index (TLI) = .91; root-mean-square error of approximation (RMSEA) = .07. Model 2 generated  $\chi^2(24, N = 715) = 176.2, p = .0001$ ; CFI = .90; TLI = .84; RMSEA = .09. Model 3 generated  $\chi^2(32, N = 715) = 208.6, p = .0001$ ; CFI = .88; TLI = .83; RMSEA = .09. Model 4 generated  $\chi^2(26, N = 715) = 303.2, p = .0001$ ; CFI = .81; TLI = .74; RMSEA = .12. While the chi-square statistic was significant for all of these models due to the large sample size in this study, Model 1 had the best fit of those tested on the basis of other indices used in this analysis. This suggests that considering these four constructs as separate latent variables is a good fit for this data.

The correlations and standardized weights from Model 1 also converged strongly with the results in Tables 3 and 4. Cognitive ability was significantly correlated with belief bias syllogisms ( $r = .57, p < .001$ ) and thinking dispositions ( $r = .44, p < .001$ ), and thinking dispositions were significantly correlated with syllogistic reasoning ( $r = .33, p < .001$ ). Further, the path coefficient from cognitive ability to heuristics and biases was significant (.32,  $p < .002$ ), the path from thinking dispositions to heuristics and biases was significant (.23,  $p < .001$ ), and the path from syllogistic reasoning to heuristics and biases was significant (.38,  $p < .0001$ ).

processes that we use to reason about what we should believe and how we should act given those beliefs. These thought processes correspond, respectively, to epistemic rationality (rationality of belief) and practical rationality (rationality of action). The distinction between epistemic and practical rationality has been much discussed in philosophy and cognitive science (Over, 2004; Samuels & Stich, 2004).

If these theorists are correct, then critical thought is rational thought—and the tasks used in our heuristics and biases battery tap some of the most important strictures of rational thinking that cognitive scientists have identified (Over, 2004; Samuels & Stich, 2004). For example, our battery examined violations of rational thinking such as conjunction errors in probability judgment, failures of descriptive invariance, ignoring sample size, failure to weight the denominator of the likelihood ratio, ignoring base rates, and failure to regress predictions (see Evans, 2007; Gilovich et al., 2002; Kahneman & Tversky, 1996, 2000; Stanovich, 1999, 2008b).

Our measure of the ability to avoid these thinking errors was moderately correlated ( $r = .437$ ) with a more traditional laboratory measure of critical thinking—the ability to reason logically when logic conflicts with prior belief. The correlation between these two classes of critical thinking skills was not due to a joint connection with cognitive ability. It remained statistically significant after the variance due to cognitive ability was partialled out (partial  $r = .321$ ,  $p < .001$ ). As the third regression in Table 3 shows, performance on the syllogistic reasoning task with belief bias predicted 8.7% unique variance ( $p < .001$ ) in performance on the heuristics and biases battery after cognitive ability was controlled, and as the fourth regression in Table 3 indicates, performance on the syllogistic reasoning task predicted 7.4% unique variance ( $p < .001$ ) in performance on the heuristics and biases battery after cognitive ability and thinking dispositions both were partialled out. As the commonality analysis in Table 4 indicates, the syllogistic reasoning task had as high a unique connection to heuristics and biases performance (7.4% variance explained) as it held in common with SAT as a predictor (7.1% variance explained).

Another triangulating conclusion that can be drawn from the commonality analysis in Table 4 is that our new class of critical thinking skills (the heuristics and biases tasks) is more specifically related to a classic critical thinking skill (the ability to reason logically when logic conflicts with prior belief) than it is to cognitive ability. The basis of this conclusion is that the unique variance in heuristics and biases performance explained by syllogistic reasoning performance (7.4%) was nearly double the unique variance explained by SAT scores (3.8%).

A notable finding of our study was that the thinking dispositions measures were independent predictors (after cognitive ability was controlled) of both classes of critical thinking skill (see the first and second regressions in Table 3). That thinking dispositions were an independent predictor of the ability to avoid bias by prior belief when reasoning converges with several previous studies. For example, Schommer (1990) found that a measure of the disposition to believe in certain knowledge predicted the tendency to draw one-sided conclusions from ambiguous evidence even after verbal ability was controlled. Kardash and Scholes (1996) found that the tendency to properly draw inconclusive inferences from mixed evidence was related to the disposition to believe in certain knowledge and to a measure of need for cognition. Furthermore, these relationships were not mediated by verbal ability because a vocabulary measure was essentially unrelated to evidence evaluation. Likewise, Klaczynski (1997; see also Klaczynski & Gordon, 1996; Klaczynski & Robinson, 2000) found that the degree to which

adolescents criticized belief-inconsistent evidence more than belief-consistent evidence was unrelated to cognitive ability (see also Perkins, Farady, & Bushey, 1991) but often was related to thinking dispositions associated with epistemic regulation. The evaluation of personally relevant arguments has been found to be related to actively open-minded thinking dispositions independent of cognitive ability (Sá et al., 1999; Stanovich & West, 1997).

The results of the first regression of Table 3—that our thinking dispositions measures predicted belief bias in syllogistic reasoning independent of cognitive ability—converges with these previous findings. What is even more notable is that the second regression in Table 3 indicates that the thinking dispositions were also unique predictors of a very different class of critical thinking skill—the susceptibility to the large class of cognitive biases discovered and reported in the heuristics and biases literature.

We wish here to introduce another class of thinking processes that needs to be considered when measuring the critical thinking abilities of individuals. Our goal has not been to develop a new critical thinking psychometric assessment instrument but, instead, to introduce theorists to a wide variety of critical thinking skills that are largely untapped by currently used critical thinking tests and to provide a preliminary indication of their likely empirical relationships to related constructs (cognitive ability and belief bias in reasoning). Typically, individual studies in the heuristics and biases literature have examined a single problem or only a few problems in an effort to understanding the processes that underlie responses that violate rational strictures (e.g., Gilovich et al., 2002; Kahneman, 2003; Kahneman & Tversky, 2000). Alternatively, the psychometric approach is characterized by the use of several similar items, which results in high internal consistency and reliability, as in measures of intelligence. In contrast, our approach has been to use a carefully selected set of different well-established heuristics and biases tasks that were expected to reflect relatively distinct cognitive skills, as opposed to a psychometric validation of a collection of problems thought to be characterized by similar reasoning tendencies. Thus, the rational thinking tendencies that we tapped with our measures reflect more than a single construct. Although some theoretical taxonomies have been proposed (Reyna et al., 2003; Stanovich 2008a, 2008b, in press; Stanovich, Toplak, & West, 2008), empirical work on construct differentiation is as yet virtually nonexistent—it is work we hope to provoke with our study. Given that we measured a multifarious concept with single tasks, the modest reliability of our heuristics and biases score was perhaps better than might have been expected. In the only studies (that we are aware of) in which multiple-item measures of different cognitive biases were used, Parker and Fischhoff (2005) and Bruine de Bruin et al. (2007) found mean interitem correlations of .12 and .16, respectively—higher than our mean of .066 but indicative that the biases are not reflective of a single underlying mechanism.<sup>4</sup> Further work will need to elaborate the structure of these biases so that they eventually might become more fully integrated with more classic notions of critical thinking which stress aspects of non-egocentric processing such as unbiased reasoning in the face of prior belief.

<sup>4</sup> An analysis of the correlation matrix in Table 2 of Klaczynski (2001) likewise yielded mean intertask correlations of roughly .15 among single-task measures of each bias when a single nonredundant variable was used for each task. Similarly, the mean correlation in a study including a battery of heuristics and biases tasks conducted by Slugoski, Shields, and Dawson (1993) was .03.

## Low Publication Prices for APA Members and Affiliates

**Keeping you up-to-date.** All APA Fellows, Members, Associates, and Student Affiliates receive—as part of their annual dues—subscriptions to the *American Psychologist* and *APA Monitor*. High School Teacher and International Affiliates receive subscriptions to the *APA Monitor*, and they may subscribe to the *American Psychologist* at a significantly reduced rate. In addition, all Members and Student Affiliates are eligible for savings of up to 60% (plus a journal credit) on all other APA journals, as well as significant discounts on subscriptions from cooperating societies and publishers (e.g., the American Association for Counseling and Development, Academic Press, and Human Sciences Press).

**Essential resources.** APA members and affiliates receive special rates for purchases of APA books, including the *Publication Manual of the American Psychological Association*, and on dozens of new topical books each year.

**Other benefits of membership.** Membership in APA also provides eligibility for competitive insurance plans, continuing education programs, reduced APA convention fees, and specialty divisions.

**More information.** Write to American Psychological Association, Membership Services, 750 First Street, NE, Washington, DC 20002-4242.

# Identifying Patterns of Appraising Tests in First-Year College Students: Implications for Anxiety and Emotion Regulation During Test Taking

Heather A. Davis  
North Carolina State University

Christine DiStefano  
University of South Carolina–Columbia

Paul A. Schutz  
University of Texas–San Antonio

The authors explored patterns of appraising tests in a large sample of 1st-year college students. Cluster analysis was used to identify homogeneous groups of 1st-year students who shared similar patterns of cognitive appraisals about testing. The authors internally validated findings with an independent sample from the same population of students and examined the extent to which cluster membership differentiated undergraduates on the basis of external indicators (e.g., anxiety, emotion-regulation strategies, and achievement). The authors used 2 randomly drawn samples to conduct an initial cluster analysis ( $n = 1,107$ ) and to replicate the solution on a 2nd, independent cluster and cross-classification analysis ( $n = 1,108$ ). There may be 5 subtypes of test takers who differ in how they approach tests, their experience of anxiety, and how they manage problems that occur during test taking. Theoretical implications for emotion and emotion regulation, as well as practical implications for working with undergraduates who experience test anxiety, are discussed.

**Keywords:** test taking, test anxiety, emotion regulation, cognitive appraisals, coping

Emotions, such as those experienced during testing, have been the subject of considerable theoretical and empirical work in the past 20 years (Ellsworth & Smith, 1988; Lazarus, 1999; Schutz & Davis, 2000; Schutz & Pekrun, 2007). This interest has emerged, in part, because of the roles that emotion and emotional regulation play in self-directed behavior. In terms of the research on emotions and emotional regulation, the area of test taking has received the most attention (Pekrun, Goetz, Titz, & Perry, 2002; Schutz & Pekrun 2007). The main focus of this research has been on the nature of test anxiety (e.g., Hodapp & Benson, 1997; Sarason & Sarason, 1990; Zeidner, 1998, 2007) and on how students cope or regulate their anxiety during the testing process (Carver & Scheier, 2000; Folkman & Lazarus, 1985; Kondo, 1997; Zeidner, 1998). This research has contributed to the understanding of emotion and emotional regulation during test taking and to the development of a context-specific, valid, and reliable measure of emotional regulation during test taking (Schutz, Benson, & DeCuir, in press; Schutz, DiStefano, Benson, & Davis, 2004). However, to date, there have been few studies (Davis, DiStefano, DeCuir, & Schutz, 2000; see also Brdar, Rijavec, & Loncaric, 2006; DeCuir, Aultman, & Schutz, in press; Rice & Slaney, 2002; Sondaite &

Zukauskienė, 2005; Tanaka, 2007) that have attempted to systematically identify whether there are group differences in the ways students approach academic tasks—specifically tests—and in the strategies they deploy to attempt to manage their emotions.

In his study of 100 high school and 241 college students, Zeidner (1996; see also Zeidner & Matthews, 2005) found that students with richer coping resources concurrently tended to report lower levels of trait anxiety and evidenced lower levels of state anxiety during an exam. Zeidner argued that testing situations contain the critical elements of major environmental stressors, including the need to prepare for an impending event, eminent confrontation with a stressor, uncertainty surrounding the outcome of the event, and the need to cope with the consequences. Students were asked to report their level of test anxiety, their coping resources, and their situational coping strategies 6 weeks prior to an exam. Dispositional judgments were then used to predict their level of state anxiety during an exam. Zeidner found that there was no relationship between the deployment of coping strategies and the resultant experience of anxiety during tests.

In the following sections, we begin by defining what emotion regulation is and how the judgments students make about test taking may contribute to a “proneness” (Zeidner, 2007, p. 167) to experience anxiety. Next, we review four theories of emotion processes as they relate to achievement activities. Each of these theories makes specific claims about which judgments, or appraisals, are the most salient in the study of achievement tasks. These theories describe the ways in which students’ perceptions ultimately affect the quality of their engagement and performance. Finally, we describe a project designed to examine the ways in which college students may approach tests in systematically different ways—and the implications of these findings for theories of

emotion regulation and for working with populations of test anxious students.

### Understanding Evaluation Anxiety and Emotion Regulation

"Evaluation anxiety can have serious consequences for one's physical and mental health as well as for one's educational achievement and occupational career" (Zeidner, 2007, p. 165). In a recent meta-analysis, Hembree (1998) found test anxiety to be negatively correlated with achievement in college and high school populations as well as being related to performance and well-being. According to Zeidner (2007), "test anxiety has been found to interfere with competence in both lab settings as well as in true-to-life test taking situations in school and college" (p. 171).

Scholars who study test anxiety tend to make at least two important distinctions. The first is to distinguish the difference between trait anxiety and state anxiety (Zeidner, 1995). The second is to distinguish between the cognitive and affective components of the anxiety experience. Zeidner (2007) described trait anxiety as reflecting individual differences in students' "prone-ness" (p. 167) toward feeling anxious during a test, with some students experiencing pervasive or excessive worry about exams even when they are not in the immediate testing situation. "Trait like affect reflects a general way of responding to the world, which varies by person, but is relatively stable over time" (Linnenbrink, 2007, p. 108; see also Rosenberg, 1998). In contrast, state test anxiety may fluctuate depending on the context of a given test and can be brought about by changes in the testing environment.

In the short-term, acute distress and worry are generated by accessing negative self-beliefs, that one lacks academic competence, for example, and by choosing counterproductive coping strategies, such as self-blame and avoidance, that focus attention on personal shortcomings in the academic domain. (Zeidner, 2007, p. 167)

In distinguishing between the cognitive and affective components of test anxiety, scholars have attempted to tease out the thoughts and beliefs that lead students to perceive threats in the testing context as somewhat distinct from the different forms of arousal (e.g., tension, bodily reactions) they may feel while taking tests. Our focus is on these self-referent thoughts and beliefs. In fact, cognitive appraisal theory suggests that the judgments students make about their testing situation serve as organizers for their affective response system (van Reekum et al., 2004).

### *Cognitive Appraisals About Tests*<sup>1</sup>

Research on cognitive appraisals has suggested that the judgments, or appraisals, people make about their environment and their ability to manage challenges/threats are related to the emotions they experience (Lazarus, 1991; Roseman & Smith, 2001; Smith, 1991). These judgments can occur rapidly and without conscious awareness but are viewed as essential for emotions to emerge (Panksepp, 2005). Appraisal theory asserts three important assumptions. First, cognitive appraisal theory assumes the appraisal process takes place continuously. Because of this, one way to regulate or manage an emotion may be to reappraise the situation, that is, to see the situation in a new light. Folkman and Lazarus (1985) published a seminal series study in which they

assessed students' emotions and coping at three phases of the examination process: anticipation of the exam, the wait for grades to be posted, and the time after grades were posted. At each stage, they were asked to describe their state of mind and rate their experience of emotions associated with perceiving threat (i.e., worry, fear, and anxiety), challenge (i.e., confidence, hope, and eagerness), harm (i.e., anger, sadness, disappointment, and guilt) and benefit (i.e., exhilaration, pleasure, happiness, and relief). They found there were significant changes in the emotions students experienced, including seemingly contradictory emotions, as well as in the coping strategies they deployed. These findings suggested that the appraisal process was ongoing, throughout the entire examination process, resulting in a fluctuating emotion experience.

Second, appraisal theory asserts that the judgments are relational to the individual with "goals provid[ing] the 'direction' in self-regulation" (Schutz & Davis, 2000, p. 245). That is why two students can look at the same test, can both perceive it as challenging, but only one may become anxious. People's cumulative histories and their beliefs about themselves contribute to the in-the-moment judgments they make and the emotions that result. In an interesting series of studies by Kondo (1997), 79 undergraduate students were asked to complete a measure of test anxiety and then to describe the tactics they used to cope with their anxiety in anticipated and actual examinations. Kondo generated a cumulative list of all strategies and then had a second set of undergraduates sort these strategies into meaningful categories. He then correlated the types of strategies deployed with the original 79 participants' anxiety scores. In addition to finding that some types of test preparation strategies were more closely associated with the experience of anxiety, Kondo found that "people with high test anxiety tended to report significantly more strategies than those with low test anxiety" (p. 210). Thus, consistent with appraisal theory, some students who experience higher test anxiety may do so as a function of holding higher standards for performance.

In the appraisal literature, Lazarus (1991, 1999) made a distinction between primary and secondary appraisals. Primary appraisals are associated with the likelihood and intensity of the emotion experience, whereas secondary appraisals are associated with flavoring the specific emotion experienced. For primary appraisals, there are two pivotal judgments, labeled *goal relevance* and *goal congruence*, which are viewed as defining the likelihood of an emotion to emerge. Goal relevance is defined as the judgments individuals make about how important events are to their goals. In other words, for test anxiety to emerge, students must judge tests, and test scores, as important to achieving their academic or personal goals. If tests are not seen as important, the potential for feeling anxiety diminishes. Goal congruence is defined as the extent to which events are perceived as aligning with individuals' goals. Events that are perceived to be in conflict with or obstacles to goal pursuit are goal incongruent. Within the testing context, the appraisal of goal congruence is related to students' perceptions of how helpful a particular test or test scores in general are in moving them closer to their goals. These goals might include acquiring a

<sup>1</sup> We thank the reviewers for their invaluable feedback about the nature of individual differences in appraising tests. Their feedback led to major revisions of the content and structure of the literature review.

specific grade in a class, graduating, or preparing for a specific career. According to appraisal theory, pleasant emotions, such as happiness or pride, are more likely to be experienced during tests that are perceived to be goal congruent, whereas unpleasant emotions, such as anxiety, anger, or shame, are more likely to emerge when tests are perceived as goal incongruent. Again, it is important to keep in mind that students use their own standards when judging whether a test is going well or poorly. Doing well for one student might involve understanding some but not all items on the test, whereas for other students, having to stop and think, or reason through, any single item on a test may feel threatening because they are using a standard of perfection or an A as their goal (Schutz & Davis, 2000).

Third, appraisal theory assumes that the secondary appraisal process is differentiated, with some judgments mattering more than others in bringing about any given emotion (Smith, Haynes, Lazarus, & Pope, 1993). Several different programs of research have attempted to develop taxonomies, or classification systems, to predict which appraisals lead to different emotion experiences (Roseman, Anoniou, & Jose, 1996; Scherer, 1988; Smith, 1991). Ben-Ze'ev (2000) provided one of the most comprehensive descriptions of the numerous different types of appraisals that have been studied to predict and describe emotion experiences.

Within the field of test taking, Schutz and Davis (2000; see also Schutz et al., 2004, in press; Smith & Ellsworth, 1987) argued that there are two key secondary appraisals involved in eliciting test anxiety: agency and testing problem efficacy. *Agency* is defined as the extent to which students appraise the outcome of a particular test as being under their control. According to Schutz and colleagues (Schutz & Davis, 2000; Schutz et al., 2004, in press), for anxiety to emerge, students must perceive a lost sense of agency related to the test. Kondo (1997) suggested that the perception of lack of control may reflect the uncertainty students feel about the extent to which their preparation efforts matched or did not match the demands of the test. In addition, *testing problem efficacy* is defined as the judgments students make about their ability to manage the problems that emerge during tests, such as not understanding a question or having to reason an answer through. They argued that anxiety is more likely to emerge when students judge they have little or no confidence in their ability to manage the problems or their emotions during tests.

Fourth, Pekrun, Frenzel, Goetz, and Perry (2007) discussed the ways in which emotions may become more "habitualized" (p. 23) as a function of repeated associations with a given situation. As emotion experiences become associated with tasks, the initial appraisal process may be short-circuited, and the appraisal processes become more consistent. In other words, when faced with a new test, students not only evaluate the demands of a specific test, but also draw on their past experiences taking tests and their past judgments of goal relevance, congruence, agency, and test problem efficacy. These patterned ways of appraising tests can help researchers understand how discrete judgments of tests can, over time, affect more general outcomes, such as achievement across courses or on standardized measures. In fact, Schutz et al. (2004) found that appraisal processes contributed to predicting between 16% and 25%, or between a half and a full letter grade, of the variance in students' self-reported college grade point average.

### *Defining Emotion Regulation and Regulating During Tests*

Emotion regulation has been defined as the physiological, behavioral, and cognitive processes that enable individuals to modulate their experiences and expression of emotions (Gross, 1999; Gross & Munoz, 1995; Gross & Thompson, 2007; John & Gross, 2004). In some cases, moderating may mean dampening, or down-regulating, the experience of an emotion, whereas in other cases, moderating may involve amplifying, or up-regulating, an emotion. Gross and Thompson (2007) noted that emotion regulation occurs on a continuum from conscious, effortful, and controlled to unconscious, effortless, and automatic. Also, it is important to understand that merely engaging in some form of regulation (i.e., deploying some strategy) can make something better or worse depending on whether the selection was appropriate or enactment was effective. Restated within the context of test taking, although some students may consciously engage in trying to reduce unpleasant feelings during tests, their enactment of specific strategies may not necessarily produce the results they desire. This is what makes studying emotion regulation so challenging. A strategy that may be defined as less adaptive by the field might actually serve a functional purpose for a given student, and strategies that have been historically defined as adaptive may not assist students in modulating their emotion experience if they are enacted poorly (John & Gross, 2007; Lazarus, 1985; Thompson & Calkins, 1996). Thompson and Calkins (1996) argued that there may be a cost-benefit trade-off for engaging in strategies aimed at preserving or changing one's sense of self. That is, strategies deployed to dampen an unpleasant emotion may provide students with a short-term benefit; however, such strategies may have the hidden consequence of diminished performance.

Gross and Munoz (1995; see also Gross & Thompson, 2007) outlined five different families of emotion-regulation strategies: situation selection, situation modification, attentional deployment, cognitive change, and response modulation. In situation selection, individuals avoid certain situations, people, or contexts to try to decrease unpleasant emotions or, in turn, seek out specific situations, people, or contexts as a way of enhancing pleasant emotions. In situation modification, people seek to assert themselves into a situation to modify that situation to meet their needs. Within the testing context, most students do not have the opportunity to engage in this type of regulation. Tests, in large part, are determined by instructors—although some instructors may be willing to negotiate format, timing, and so forth. In attentional deployment, individuals try to focus on more or less valued aspects of the context to up- or down-regulate an emotion. The goal is either to distract themselves from or to concentrate on elements of the situation. Davis, Schutz, and DeCuir (1999) found that students with lower levels of test anxiety used attentional deployment to regulate their experience of anxiety by concentrating first on the easy questions on tests and then returning to work on harder questions. In many cases, this helped to reduce the students' anxiety because they could compare the numbers of easy and hard questions, and they felt confident about their understanding of the material (i.e., given their responses to easy questions) by the time they began working on more challenging questions. In cognitive change, individuals try to construct a more positive meaning out of their experience, for example, by reappraising the relative impor-

tance or value of the situation. Each of these four types of regulation strategies could be considered antecedent-focused strategies, in that, when deployed, their intent is to try to alter some element of the context, beliefs, or judgments that bring about the emotion experience. In contrast, in response modulation, individuals attempt to work on the emotion experience by trying to suppress or extract the emotion they feel. Although many scholars have studied each of these strategies, both in lab and naturalistic settings, Gross and Thompson (2007) noted, "One important and as yet unanswered question is how different forms of emotion regulation typically co-occur" (p. 17).

Within the field of emotion regulation, the largest body of literature exists in the area of coping (Lazarus & Folkman, 1984, 1991). Lazarus (2001) defined coping as "the effort to manage psychological stress" (p. 45). Early work in the field of coping identified two different forms of coping—problem focused and emotion focused (Carver, Scheier, & Weintraub, 1989). In problem-focused coping, individuals deploy strategies to manage the demands of the task, whereas in emotion-focused coping individuals deploy strategies to modulate the emotion experience. According to several studies aimed at developing measures to capture coping, some individuals tend to deploy, and even rely on, certain strategies in certain situations (Carver & Scheier, 2000). Moreover, a large body of research has indicated that there may be consequences for reliance on emotion-focused coping strategies, such as higher reports of depression (Rafnsson, Jonsson, & Windle, 2006) and unpleasant emotions like anger (Martin & Dahlen, 2005). In fact, most researchers in the field of coping have suggested that problem-focused coping strategies are generally more productive or adaptive (Moos & Holahan, 2003).

Within the field of test taking, Schutz and colleagues (Schutz & Davis, 2001; Schutz et al., 2004, in press) have identified three different dimensions of coping that students use to manage problems during tests: task-focused processes, regaining task focus, and emotion-focused processes. The key element of task-focused processes is that the focus of students' internal talk is the strategies they are using during the task. For example, during testing, students' task-focused thoughts might be about how to manage their time during the test or about looking for answers to one question in another. These thoughts help to keep students focused on the test and away from potentially disruptive thoughts about themselves. In keeping with the work of Gross and colleagues (Gross, 1998, 2002; Gross & Munoz, 1995; Gross & Thompson, 2007), task-focused processes largely reflect students' attempts at attentional deployment. In this case, students focus on those elements of the test they can control: reading the directions, finding main ideas in the questions, eliminating responses, and so forth. This shift in concentration away from what confuses them and onto what they understand not only regulates the emotion, but also manages the actual demands of the test.

Aligned with earlier research on coping, the second dimension of emotion-focused processes involves a shift in students' focus from the task to themselves and the emotions related to the task. It involves a disengagement from the task and a focus on their feelings and thoughts about their performance on the task and the potential causes for that performance. These emotion-focused thoughts tend to distract the examinee from the task and may lower achievement. In keeping with the work of Gross and colleagues (Gross, 1998, 2002; Gross & Munoz, 1995; Gross & Thompson,

2007), emotion-focused coping strategies also largely appear to reflect attempts at attentional deployment (to focus on how teachers may score the test or events outside of the testing context) or cognitive change (to change the meaning of challenges on a test by assuming responsibility for not preparing).

Last, Schutz et al. (2004, in press) argued that a third dimension exists, called regaining-task-focus processes. This dimension comprises processes that involve students' attempts to get back on task by attempting to reduce their tension or put the test in perspective. As such, these processes tend to be neither completely task focused nor completely emotion focused. In keeping with the work of Gross and colleagues (Gross, 1998, 2002; Gross & Thompson, 2007), these two strategies appear to target different families, with tension reduction reflecting students' attempts at response modulation (i.e., suppressing unpleasant feelings) and importance reappraisal reflecting students' attempts at cognitive change (i.e., reconstructing the meaning of the test in their lives).

### Theorizing Systematic Differences in Emotional Regulation During Testing

The purpose of this project was to explore whether students evidence habitual patterns of appraising tests that might make them more prone to experiencing anxiety during tests. In the following sections, we briefly review three theories of emotionality in education that have important implications for understanding why anxiety might emerge during a test, how the experience of anxiety during a test might be interpreted, and how students might systematically differ in their approaches toward tests and their attempts to modulate the experience of test anxiety.

#### *Circumplex Model of Affect*

In her circumplex theory of emotions in education, Linnenbrink (2007), building on the work of Barrett (2006) and Russell and Barrett (1999), described the relationship between emotions and motivation as a function of valence, what we have thus far been referring to as goal congruence, and activation. She defined activation as the experience of "arousal, mobilization, and energy" (p. 108). That is, emotions that are activating have a directional component that can compel students toward or away from different activities, tasks, or behaviors. Furthermore, Linnenbrink described the ways emotions affect people's behavioral and cognitive engagement depending on whether they are pleasant or unpleasant (i.e., valence) or activating/deactivating. *Behavioral engagement* is defined as the amount and quantity of effort or persistence students put into a task (Barrett, 2006; Russell, & Barrett, 1999). *Cognitive engagement* is defined as the quality of students' thinking while they are engaged in the tasks.

Reviewing lab studies in psychology and across several of their own projects, Linnenbrink (2007) examined the extent to which pleasant and unpleasant emotions have contributed to different forms of engagement with somewhat inconsistent findings. She reviewed several laboratory studies of unpleasant emotions where researchers found that unpleasant affect led students to attend to the task/details more carefully. However, Linnenbrink, Ryan, and Pintrich (1999; see also Linnenbrink & Pintrich, 2002) found in their own work that unpleasant emotions were negatively related to students' working memory functioning and learning. Findings

from this model led us to wonder if apparently inconsistent findings regarding the connection between emotion and learning may reflect the interplay of activating emotions and the strategies they activate. In other words, for some students, activating unpleasant emotions during tests may lead to enhanced performance because those emotions activate students to engage strategies that are task focused. On the other hand, for some students, activating unpleasant emotions during tests may impede performance because those emotions may activate students to use less productive, more emotion-focused strategies. Thus, according to Linnenbrink's research, students who evidence anxiety during tests should also evidence different patterns of coping compared with students who do not (Barrett, 2006; Russell, & Barrett, 1999). Moreover, inconsistent findings across the literature on test performance suggest that there may be multiple patterns of coping and performance, with higher performing groups activating adaptive task-focusing and regaining-task-focusing processes and others activating more emotion-focused processes.

### *Control-Value Theory of Achievement Emotions*

In their control-value theory of achievement emotions, Pekrun et al. (2007) defined *achievement emotions* as those "tied directly to achievement activities or achievement outcomes" (p. 15). Pekrun and colleagues (Pekrun, 2000; Pekrun et al., 2002, 2007) developed a taxonomy of achievement emotions along three dimensions: valence, activation, and control. Aligned with Linnenbrink (2007), their framework posits that anxiety is an outcome-oriented achievement emotion that has an unpleasant valence and serves an activating function. However, they further argued that any exploration of achievement emotions must include the dimension of control. Thus, control-value theory adds to the understanding of systematic differences in students' approaches toward tests by positing that students who perceive tests as within their control are likely to evidence different patterns of anxiety, coping, and achievement.

Pekrun and colleagues (Pekrun, 2000; Pekrun et al., 2002, 2007) outlined three types of subjective control expectancies: action-control expectancies, action-outcome expectancies, and situation-outcome expectancies. Action-control expectancies include students' belief that "an achievement activity can be successfully initiated and performed" (Pekrun et al., 2007, p. 18). These types of expectancies parallel the self-efficacy types of beliefs that Bandura (1977) described in his theory of personal agency. Action-outcome expectancies include students' beliefs that their "activities lead to outcomes one wants to attain" (Pekrun et al., 2007, p. 18). From the perspective of cognitive appraisal theory, action-outcome expectancies parallel agency/control appraisals (Schutz & Davis, 2000; Smith, 1991). Finally, situation-outcome expectancies reflect beliefs "that these outcomes occur in a given situation without one's action" (Pekrun et al., 2007, p. 18). Thus, from the perspective of cognitive appraisal theory, action-outcome expectancies parallel future-expectancy appraisals (Smith, 1991). In their research, Pekrun et al. (2007) identified that dimensions of perceived control and perceived value were both necessary to predict which achievement emotions were likely to arise. Students' perceptions of control may also have important implications for the types of strategies they select to regulate their emotions (Boekaerts, 2007). Specifically, students who perceive themselves as

being in control of their test scores may be more likely to select more task/problem-focused coping strategies. Likewise, do students who perceive themselves as not in control of their test scores select more emotion-focused coping strategies?

Consistent with work by Gross (2002) and Lazarus (1999), Pekrun et al. (2007) outlined four targets of students' efforts to regulate emotions. They argued that students can gear their regulation efforts toward managing the emotion itself, toward the appraisals that underlie the emotions and the competencies that underlie students' judgments of agency, or toward modifying the environment. What is unique about their model of regulation is their discussion of how students might regulate their emotions by improving their competency. Consistent with Gross and Munoz (1995; Gross & Thompson, 2007), this behavior reflects a type of situation modification in which students attempt to assert themselves into the situation by modifying what they know or the strategies they use. Few, however, have studied the extent to which strategies used during the test may contribute to later competency building.

### *Dual-Processing Self-Regulation Model*

Boekaerts (1993; see also Boekaerts, 2007) outlined a dual-processing approach for understanding how students' appraisals of academic situations might lead to two different pathways: a growth pathway and a well-being pathway. In her theory, Boekaerts moved beyond a simple analysis of value and importance to argue that the critical appraisal students make about their academic tasks is the extent to which the task is congruent with their goals (i.e., whether the task aligns with their personal and academic goals). Academic tasks may be important for a variety of reasons, but the extent to which tasks align with students' goals can set them on two entirely different self-regulatory pathways. In the growth pathway, students appraise the academic task as aligned with their goals, and they are more likely, when faced with stress, to select strategies that refocus them on the learning goals. In contrast, in the well-being pathway, students appraise the mismatch (i.e., incongruence) between the task and their goals as a warning signal that something is "wrong" (Boekaerts, 2007, p. 39). When faced with stress, students are more likely to select strategies (e.g., avoiding, distancing, working to preserve one's sense of self) that redirect their attention away from learning goals. Boekaerts (1993, 2007) noted there are likely to be individual differences in the amount of unpleasantness, or stress, students are likely to tolerate in academic tasks—with some students being more prone to switch paths from growth to well-being, because they cannot tolerate much stress. Dual-processing theory contributes to the understanding of how students' judgments of congruence can lead them to select coping strategies that are more or less oriented toward growth.

From this perspective, we expected to find groups of students evidencing a growth pathway, whereby appraisals of tests as goal congruent would be associated with selecting coping strategies oriented toward growth, that is, more task-focused strategies. Although habitual appraisals of tests as goal incongruent would be associated with selecting coping strategies that preserve well-being, this is wishful thinking and importance reappraisal. Moreover, we wondered if students who were less tolerant of stress in

testing situations could be identified on the basis of their patterns of appraising tests.

### Purpose

The overall purpose of this study was to explore whether groups of students share similar patterns of appraising tests and to examine whether these patterns evidenced different consequences for students' (a) experience of anxiety during test taking, (b) deployment of emotion-regulation strategies, and (c) academic achievement. Ultimately, we hope to examine the ways in which some students' appraisals of tests, in general, may make them more prone to experience state anxiety during tests. Furthermore, we hypothesize that students' deployment of strategies to regulate anxiety during tests may be, in part, a reflection of their beliefs about tests and about themselves as test takers. This is an exploratory study in that (a) to our knowledge, there has never been a clustering of students on appraisal dimensions nor has there been an examination of the coping strategies associated with different patterns and (b) we had no *a priori* hypotheses as to how many clusters we would find and how patterns of judgments would cluster together. On the other hand, there is a growing body of literature from which to make hypotheses about what types of differences we might find. This is where we drew from the circumplex (Barrett, 2006; Linnenbrink, 2007; Russell, & Barrett, 1999), control value (Pekrun et al., 2007), and dual-processing (Boekaerts, 2007) theories to make general suggestions about differences.

We drew from Schutz and colleagues' (Schutz & Davis, 2000; Schutz & DeCuir, 2002; Schutz et al., 2004, in press) theory and measures of emotion regulation during testing because they contained dimensions/subscales that captured the different judgments implicated by the literature. In many ways, their theory represents a bridge across the other three theories in that it contains two dimensions of valence (importance and congruence) and, in doing so, may enable us to explore the extent which students' appraisals of test taking lead them to have qualitatively different types of engagement during tasks. Additionally, their scale includes two different dimensions of control expectancies: action control (i.e., the agency scale) and action outcome (i.e., the testing problem efficacy scale). By examining two dimensions of control, we may come to better understand why students choose to deploy some strategies over others, as well as the functions each strategy may serve in regulating emotions during testing.

This project consisted of three phases of analysis. In Phase 1, our goal was to identify a theoretically defensible cluster solution that would replicate in a second independently clustered sample. Specifically, clustering students along the four appraisal dimensions, we identified a five-cluster solution that appeared both empirically and theoretically defensible. In Phase 2, our goal was to see if the solution identified in Phase 1 would replicate in a second sample. Specifically, we clustered Sample 2 into five clusters and compared across the solutions to see if the same clusters appeared. In the event of parallel solutions, we then submitted both samples to a cross-classification validation analysis. This type of analysis generates a prediction rule off the first sample and applies it to classify the second sample. Classification assignments can then be compared with the independent clustering assignment generated for Sample 2. In Phase 3, our goal was to examine the extent to which different patterns of

appraising tests predicted differences in anxiety and emotion-regulation strategies. Specifically, in this analysis, we used a five-cluster solution built from the entire data set ( $N = 2,215$ ), generated theoretically driven hypotheses about the differences we might find, and completed a series of analyses to externally validate the five-cluster solution.

### Method

#### Participants

Prior to the start of their first year at college, the incoming class ( $n = 5,872$ ) of first-year students (ages 18–19 years) at a large Southwestern university completed a battery of assessments, including the Learning and Study Strategies Inventory (Weinstein & Palmer, 2002; Weinstein, Palmer, & Hanson, 1995; Weinstein, Palmer, & Schulte, 1987), which is a measure of learning strategies used and test anxiety experienced while in high school, and the Emotional Regulation During Test Taking Scale (ERT; Schutz et al., 2004).<sup>2</sup> The sample included slightly more female (56%) than male (44%) students. In addition, data from the state department of education were compiled for all students, including Verbal and Quantitative scores for the Scholastic Aptitude Test (SAT), percentile rank in high school, and first-semester college grade point average. Students with incomplete profiles were excluded from analyses. The final sample size for this study was 2,215.

#### Measures

To identify homogeneous groups of students on the basis of their patterns of appraisal, we submitted undergraduate students' responses to Cognitive-Appraising Processes subscales of the ERT (Schutz et al., 2004) to cluster analysis. Students were asked to think about tests and test taking in general when responding to ERT items. Responses were given on a Likert-type response scale with five options: 1 (*almost never*), 3 (*sometimes*), and 5 (*almost always*); Options 2 and 4 were unlabeled.

*Capturing students' cognitive appraisals for tests.* Items on the Cognitive-Appraising Processes subscales of the ERT are designed to measure the four discrete judgments students may make about tests. These subscales include Goal Importance (4 items), Goal Congruence (4 items), Agency (4 items), and Testing Problem Efficacy (4 items). Goal Importance items ask students to identify the extent to which test taking is important for meeting their goals (e.g., "My test performances are important for getting my degree."). Our sample yielded an alpha of .79. Items on the Goal Congruence subscale are designed to capture the extent to which students perceive their grades on tests as helping them to accomplish their goals (e.g., "My grades on tests are helping me get my degree."). Schutz et al. (2004) reported internal consistency estimates of  $r = .80$  for Goal Congruence items. Our sample yielded an alpha of .76. Items on the Agency subscale capture the extent to which students perceive that they are in control of the outcome of their tests (e.g., "It is my own fault if I don't do well on tests."). Schutz et al. reported internal consistency estimates of

<sup>2</sup> Only the Test Anxiety subscale of the Learning and Study Strategies Inventory was used in the project. The other subscales fell outside the scope of this article.

$r = .85$  for agency items. Our sample yielded an alpha of .73. Finally, items on the Testing Problem Efficacy subscale evaluate the extent to which students feel confident they are capable of managing the problems that emerge during test taking (e.g., "Even when there are difficult questions, I can usually figure out how to answer them."). Schutz et al. reported internal consistency estimates of  $r = .79$  for the Testing Problem Efficacy subscale. Our sample yielded an alpha of .75.

*Concurrent measures.* In Phase 3, we examined the validity of our replicated cluster solution by examining the extent to which students with similar patterns of appraisal for tests experienced distinct patterns of anxiety, emotion regulation, and achievement. For these analyses, we examined differences among clusters, using information that was not included in the cluster analysis. These variables included students' scores on the Test Anxiety subscale of the Learning and Study Strategies Inventory, their scores on the coping dimensions of the ERT, and achievement data from their college records. The Test Anxiety scale of the Learning and Study Strategies Inventory (Weinstein et al., 1987) comprises nine items assessing the degree to which students worry about their academic performance. For example, items address the extent to which worrying about performance during a test tends to interfere with students' concentration.

Students' scores on this scale measure how tense or concerned they are when approaching academic tasks. Students who score low on this measure (indicating high anxiety) need to learn techniques for coping with anxiety and reducing worry so that they can focus on the task at hand and not on their anxiety. (Weinstein & Palmer, 2002, p. 9)

Weinstein et al. (1987) reported an internal consistency estimate of  $r = .87$ . Our sample yielded an alpha of .85.

The ERT comprises five types of processes organized around three dimensions of emotion regulation related to test taking. Four items were used to assess the task-focusing processes dimension (e.g., "I work harder to find the main idea in the questions."). Schutz et al. (2004) reported internal consistency estimates of  $r = .57$  for the Task Focusing subscale. Our sample yielded an alpha of .59. Two subscales attempted to capture the regaining-task-focusing processes dimension. These included Tension Reduction (4 items; e.g., "I try to slow down my breathing.") and Importance Reappraisal (5 items; e.g., "I try to keep the test's importance in perspective with the other factors in my life."). Schutz et al. reported internal consistency estimates of  $r = .77$  and  $r = .72$  for the Tension Reduction and Importance Reappraisal subscales, respectively. Our sample yielded alphas of .63 and .67, respectively. Last, two subscales were designed to capture an emotion-focused processes dimension. These included the Wishful Thinking subscale (4 items; e.g., "I hope the teacher decides not to count the test.") and the Self-Blame subscale (4 items; e.g., "I blame myself for the problems I am having on the test."). Schutz et al. reported internal consistency estimates of  $r = .77$  and  $r = .86$  for wishful thinking and self-blame subscales, respectively. Our sample yielded alphas of .77 and .83, respectively.

In addition, at the end of the survey, participants were asked to self-report their age and their gender. These data were merged with data from the institution's database containing students' SAT Verbal and Quantitative scores, their relative rank in high school, and their first semester college grade point average.

## Procedures

*Phase 1: Independent cluster analysis.* Following procedures outlined by DiStefano and Kamphaus (2006), the larger sample of students was divided into two randomly drawn subsamples: an initial sample (used for an initial cluster analysis;  $n = 1,107$ ) and a second sample ( $n = 1,108$ ) used for a second, independent cluster analysis and a cross-classification internal validation. Cluster analysis refers to a set of procedures used to uncover homogeneous groups underlying a data set (Aldenderfer & Blashfield, 1984; Anderberg, 1973; Blashfield & Aldenderfer, 1988; DiStefano & Kamphaus, 2006; Milligan & Cooper, 1987). Our goal was to identify smaller subgroups of first-year college students who are similar, with regard to their judgments of tests, to members within their cluster while distinct from members of the other clusters. To achieve this goal, we used a two-step procedure in our initial cluster analysis that combined Ward method and K-means algorithms to attempt to overcome the limitations of each method when selected as the sole method (DiStefano & Kamphaus, 2006). To guide our selection of a clustering solution for Sample 1, we began by examining the cubic clustering criterion (CCC) plots to determine the number of potential clusters underlying our data. This criterion indicated there might be between four and six clusters embedded in the data. Therefore, on the basis of these plots, we ran four- through seven-cluster solutions for the initial solution. Each solution was scrutinized to the extent that we could identify unique patterns of the four appraisals for tests. To facilitate interpretation, we graphed both raw and standardized scores. Although raw scores assisted us in understanding the magnitude of students' reports; standardizing the scores assisted in interpreting the relative magnitude of each cluster's reports. Once we failed to recognize unique solutions—in other words, one cluster appeared to split into two—we chose to stop interpreting new solutions. From these clustering procedures, we identified a five-cluster solution as optimal (see Table 1 and Figure 1).

*Phase 2: Replication and cross-classification.* To explore the validity of the five-cluster solution generated in Sample 1 ( $n = 1,107$ ), Sample 2 ( $n = 1,108$ ) was independently clustered into five clusters to determine whether the same five-cluster solution could be replicated. We repeated the clustering procedures from Phase 1, considering Sample 2 an independent analysis, and examined (a) whether the same number of clusters were present in the data and (b) whether the patterns of cognitive appraisal found in Sample 2 reflected patterns similar to those found in Sample 1 (see Table 2, Figure 2).

Next, a classification rule, developed from the initial five-cluster solution, was used to classify cases in Sample 2. Hit rates for correctly and incorrectly classified cases across the five clusters were compared (Huberty, 1994). High hit rates indicate that the rule generated from Sample 1 predicted students' actual cluster assignment for Sample 2. Findings from the cross-classification enabled us to examine the extent to which the rule developed in Sample 1 could replicate patterns found in Sample 2. The use of these two methods allowed us to examine the data for sample-specific characteristics to determine the extent to which clusters represented unique, stable groups that may exist in the larger population of first-year college students (See Table 3).

*Phase 3: Examining the corollaries of different patterns of appraising tests.* To explore the external validity of the five-cluster solution, we examined whether uniquely different patterns

Table 1  
Cluster Centroid Values for the Initial Five-Cluster Appraisal Solution

Test appraisal	Cluster centroid value					Sample mean
	Cluster 1 (n = 199)	Cluster 2 (n = 257)	Cluster 3 (n = 277)	Cluster 4 (n = 155)	Cluster 5 (n = 219)	
Goal relevance	15.32 (0.68)	11.77 (-0.43)	12.51 (-0.20)	8.54 (-1.44)	16.87 (1.16)	13.15
Goal incongruence	15.20 (0.50)	12.81 (-0.30)	12.23 (-0.16)	9.37 (-1.46)	17.08 (1.13)	13.71
Agency	16.68 (0.19)	17.75 (0.62)	13.82 (-0.95)	14.97 (-0.49)	17.81 (0.65)	16.20
Testing problem efficacy	10.88 (-0.98)	15.46 (0.74)	12.67 (-0.31)	12.18 (-0.50)	15.57 (0.77)	13.50

Note. Standardized scores are presented beside each raw value in parentheses.

of cognitive appraisals during test taking were associated with uniquely different patterns of anxiety, emotion regulation, and achievement by examining variables, which were not included in the clustering process. To determine the extent to which groups were different, one-way analyses of variance (ANOVAs) were conducted between clusters where anxiety, coping, and achievement measures (i.e., SAT, high school and college standing) were considered the dependent variables. If an omnibus ANOVA test illustrated statistically significant differences among the clusters, follow-up tests were run with Tukey's post hoc procedures, controlling the error rate to .05, to identify statistically different (as well as similar) clusters. For variables in which the assumption of homogeneity of variance was violated, Dunnett's post hoc test for unequal variances was used.

## Results and Discussion

### Phase 1: Initial Cluster Analysis

Findings from the independent cluster analysis are presented in Table 1. To assist with comparing what makes each cluster unique, Figure 1 portrays each cluster's standardized score along the four appraisals. Regarding first-year college students' cognitive appraisals about tests, our findings yielded five unique patterns of appraisals. Here we describe each cluster.

*Cluster 1.* In general, students in this cluster were characterized by moderate levels of goal importance, goal congruence, and agency. According to their raw data, they perceived tests as important and their scores on tests as generally helping them to achieve their goals. Relative to the other clusters, their appraisals

Figure 1. An examination of patterns of cognitive appraisals for the initial five-cluster solution (Z scores). To assist with comparison, scores on the four cognitive appraisal scales were converted to standardized scores. Note that higher scores on the Learning and Study Strategies Inventory Test Anxiety scale reflect lower rates of test anxiety.

Table 2  
Cluster Centroid Values for the Replication Five-Cluster Appraisal Solution

Test appraisal	Cluster centroid value					Sample mean
	Cluster 1 (n = 264)	Cluster 2 (n = 268)	Cluster 3 (n = 214)	Cluster 4 (n = 166)	Cluster 5 (n = 196)	
Goal relevance	15.17 (0.65)	12.39 (-0.20)	11.46 (-0.47)	8.17 (-1.47)	16.88 (1.16)	13.04
Goal incongruence	14.96 (0.44)	13.49 (-0.04)	12.26 (-0.44)	9.05 (-1.50)	17.31 (1.21)	13.61
Agency	15.90 (-0.15)	17.37 (0.42)	13.85 (-0.95)	15.63 (-0.26)	18.54 (0.87)	16.29
Testing problem efficacy	12.20 (-0.50)	15.69 (0.79)	11.37 (-0.81)	12.91 (-0.24)	15.40 (0.68)	13.56

Note. Standardized scores are presented beside each raw value in parentheses.

of goal importance and congruence were relatively high. However, their slightly higher levels of goal importance and congruence were paired with lower levels of agency and efficacy. Although these students tended to report feeling in control of their outcomes on tests, they reported feeling the least confident to manage problems that emerged during tests.

**Cluster 2.** In general, students in this cluster were characterized by moderate levels of all the appraisals. However, relative to the other clusters, their appraisals of goal importance and goal congruence were somewhat low and were paired with higher relative reports of agency and test problem efficacy. In fact, these students reported the highest levels of both agency and problem efficacy. Thus, although students in this cluster reported that their test scores did not always help them achieve their goals, they

perceived that they were in control of their outcome and were able to manage the problems that emerged.

**Cluster 3.** Although students in Cluster 3 reported relatively moderate levels of goal importance, goal congruence, and problem efficacy, they were defined by having the lowest levels of agency. Thus, students in this cluster believed tests were relatively important, that their scores generally helped them accomplish their goals, and that when faced with problems on tests they were somewhat able to manage them. However, students in this cluster reported that they generally did not feel in control of their test scores.

**Cluster 4.** These students were characterized by the lowest rates of goal importance and congruence. Thus, students in this cluster generally did not view tests as important to their goals, nor

Figure 2. An examination of patterns of cognitive appraisals for the five-cluster replicated solution (Z scores). To assist with comparison, scores on the four cognitive appraisal scales were converted to standardized scores. Note that higher scores on the Learning and Study Strategies Inventory Test Anxiety scale reflect lower rates of test anxiety.

%	100.0	100.0	100.0	100.0	100.0	100.0

*Note.* Columns = assignments of validation sample (Sample 2 data) by independent clustering method; rows = assignment of validation sample (Sample 2) based on the classification rule developed from Sample 1. % = percentages within validation sample for independent clustering. Values in bold indicate the hit rate for each cluster, that is, the number and relative percentage of students who were accurately classified with the prediction rule.

did they view their scores as helping them accomplish their goals. It is interesting that, relative to the other clusters, the students in this cluster reported moderate levels of agency and congruence. Thus, although they did not tend to perceive tests as important or goal congruent, they reported feeling relatively in control of their outcomes and able to manage the challenges that arose during tests.

*Cluster 5.* Students in this cluster reported the highest levels of all four appraisals. Although their reports of problem efficacy were relatively high compared with the other clusters, relative to their reports of goal importance, congruence, and agency, their feelings of problem efficacy were surprisingly low. Thus, despite feeling in control of test outcomes, these students reported some uncertainty about their ability to manage problems that emerged during tests.

### *Phase 2: Replication and Cross-Classification*

To validate the solution, an independent sample (Sample 2) was first clustered to determine whether the same five clusters could be replicated. Again, the same procedures were used to cluster the data, with four- through seven-cluster solutions run and interpreted. On the basis of the independent sample analysis, we felt confident that a five-cluster solution was again optimal. Findings from the independent clustering of Sample 2 are presented in Table 2. To assist the reader with interpretation, clusters in the replication sample (Sample 2) were named to be aligned and presented in the same order as the solution generated in the initial cluster (Sample 1).

Regarding the interpretation of the new five-cluster solution (see Table 2), we felt confident that the substantive patterns of appraisals and emotion regulation existed in both samples. Four of the five

clusters were easily identifiable and evidenced nearly identical patterns of appraisal across the two samples. The only cluster we had some concern about was Cluster 1. On the one hand, this cluster evidenced a similar relative pattern of cognitive appraisals, with generally moderate levels of goal importance, goal congruence, and agency and relatively higher reports of goal importance and congruence compared with agency and problem efficacy. What did not appear to replicate from the first sample were the lower reports of test problem efficacy. Thus, in the replication sample, students did tend to report being among the least confident for dealing with the problems that emerge during tests. However, their reports, relative to the initial sample, were not as low.

Next, to provide additional validation evidence, we used a cross-classification procedure to determine if a classification rule developed from the initial five-cluster solution could accurately classify students into the five groups as well as independent clustering. The extent to which both solutions (i.e., cross classification and independent clustering) produce similar results supports the existence of the five clusters of appraisal. As previously discussed, it is common to apply a classification rule built on an existing cluster solution to classify ungrouped cases. The classification rule is based on predictive discriminant analysis in which the linear classification function is used to predict membership of an ungrouped case by assigning each case to the cluster with which it is most closely associated (Huberty, 1994; Huberty, DiStefano, & Kamphaus, 1997). Prediction of cluster membership requires information from the original sample, including cluster membership of the grouped cases and probability information relaying the likelihood of encountering a certain subgroup of children in the population. The classification rule uses a combination of the def-

inition of the cluster solution and prior probability information to classify a case into the cluster with which it is most closely associated. We may compare results between cases assigned with the classification rule and those assigned through independent clustering to determine if children were assigned to similar clusters. If cross-classification results for students classified with the rule built on the initial sample are similar to results from independent clustering, this provides confidence that a student would have received the same or a similar cluster assignment regardless of the grouping method used to classify the data. The use of these two methods allowed us to examine the data for sample-specific characteristics to determine the extent to which clusters represent unique, stable groups that may exist in the larger population.

To examine the extent to which the rule developed in Sample 1 could replicate patterns found in Sample 2, a  $5 \times 5$  table was constructed and is reported in Table 3. In Table 3, rows correspond to the cluster solution when cases were assigned with the classification rule. Columns in Table 3 correspond to the cluster assignments achieved with the independent sample solution. The table can be interpreted by reading down a column to determine categorization of students by use of the classification rule built on the initial sample, or it can be interpreted by reading across a row to determine categorization by independent clustering of Sample 2. The hits along the main diagonal can be calculated and compared with the misses or off-diagonal elements. Hit rates were computed by taking the number of cases classified into the same cluster by both methods (i.e., those correctly classified), divided by the cluster sample size from the independent clustering. Again, high hit rates indicate the rule generated from Sample 1 predicted students' membership accurately with their actual cluster assignment for Sample 2.

To assist in judging the adequacy of results, criteria were developed by Huberty (1994; see also Huberty et al., 1997) to guide evaluation. Hit rates showing at least 75% agreement between the two classification methods are thought to represent high agreement between the two methods, hit rates with between 50% and 74% agreement represent moderate agreement, hit rates with between 30% and 49% agreement denote fair agreement, and hit rates with lower than 30% agreement represent poor agreement between the classification methods.

The cross-classification analysis detailed in Table 3 showed that most of the students were correctly classified into their assigned group. In fact, four of our five clusters evidenced a high degree of agreement across the two samples. Only one cluster, Initial Cluster 1, evidenced moderate levels of agreement. In part, these lower rates may reflect that the rule was generated on a cluster solution that evidenced much lower reports of testing problem efficacy than in the replication sample. Thus, students who did not fit this rule were most likely to be misclassified into Cluster 3. This is because the students in Cluster 3 similarly reported lower levels of testing problem efficacy.

### *Phase 3: Examining the Corollaries of Different Patterns of Appraising Tests*

Again, the purpose of these analyses was twofold. First, because we were able to find the same five-cluster solution in both samples, we wanted to verify that when the two samples were pooled, the same solution would emerge. In some instances, when samples are

pooled together, new clusters may emerge (DiStefano, Kamphaus, Horne, & Windsor, 2003). Thus, finding the same five clusters again would indicate the robustness of the solution. In addition, by pooling the samples together, we might reduce the sample-specific variations that led to the lower hit rates for Cluster 1.

Second, given our ability to replicate the solution, we wanted to examine whether the five uniquely different patterns of cognitive appraisals during test taking were associated with uniquely different patterns of anxiety, emotion regulation, and achievement. To determine the extent of differences among groups, one-way ANOVAs were conducted between clusters where anxiety, coping, and achievement measures (i.e., SAT, high school and college standing) were considered as the dependent variables. To minimize the sample-specific characteristics, particularly for the one cluster that evidenced slightly lower hit rates, we pooled the two samples together, using the assignments/labels from the initial sample as the referent group. Prior to running these analyses, we made a priori hypotheses about the differences we might find.

We began this phase of the analysis by pooling the two samples together and conducting a third, independent cluster analysis. Again, we identified a five-cluster solution as the best fit and determined that the same five clusters from Phase 1 and Phase 2 existed in the pooled sample (see Table 4, Figure 3). With our increased confidence about the existence of the five-cluster solution, we proceeded with naming and describing each cluster. Then, we moved forward with making some a priori hypotheses about distinctions we might find in the ways these students approached regulating unpleasant emotions, like anxiety, that emerge during tests.

### *Hypothesizing Differences in Patterns of Anxiety, Emotion Regulation, and Achievement*

According to Schutz and colleagues' (Schutz & Davis, 2000; Schutz et al., 2004, in press) theory of emotion regulation during test taking, students who perceive tests as relevant to accomplishing their goals, their scores as obstacles to achieving their goals (i.e., incongruent), and themselves as out of control with regard to their scores (i.e., agency) and managing problems during the test (i.e., problem efficacy) are likely to experience anxiety during tests. From this perspective, we hypothesized that two clusters—Clusters 1 and 3—were likely to evidence higher rates of anxiety, relative to the other clusters. This is because both clusters reported that they perceived tests as important and scores as somewhat congruent but also perceived loss of agency or lower efficacy in managing problems during tests. Additionally, we were curious about how much anxiety students in Cluster 5 reported. Although these students reported the highest rates of goal congruence, they also reported corresponding lower perceptions of agency and efficacy. We wondered if this cluster might include students with much higher standards for performance who may experience anxiety when faced with having to think, or reason through, challenging questions on tests.

Drawing from circumplex theory (Barrett, 2006; Linnenbrink, 2007; Russell & Barrett, 1999), Pekrun et al.'s (2007) control-value theory, and Boekaert's (2007) dual-processing theory, we hypothesized specific differences we might find across the clusters in anxiety, regulation, and achievement. Linnenbrink (2007) argued that anxiety is a negatively valenced, activating emotion. From this perspective, we hypothesized that Clusters 1 and 3

would report patterns of regulation during tests that evidence active coping. Active coping on the ERT scale might reflect the deployment of task-focusing and/or tension-reduction strategies. Pekrun et al. argued that students who perceive themselves as being in control of their test scores may be more likely to select more task/problem-focused coping strategies. Thus, we hypothesized that we would find higher rates of task-focusing processes in Clusters 2 and 5. Pekrun et al. also outlined how students might gear their regulation efforts at managing the appraisals that underlie the emotions and the competencies that underlie students' judgments of agency. From this perspective, students who perceive themselves to be out of control, with regard to their tests scores (i.e., action outcome) or problems during tests (i.e., action control), might target their regulation strategies toward reappraising the importance of the tests. Specifically, we hypothesized that we would find higher reported use of importance reappraisal in Clusters 3 and 4. Boekaerts argued that students who perceive tests as obstacles to achieving their goals would choose regulation strategies that attempt to preserve their sense of well-being, whereas students who perceived tests as helping them achieve their goals would be select strategies that create opportunities for further growth. On the basis of Boekaert's theory, we identified two clusters that appeared to be on a growth path: Cluster 2 and Cluster 5. We hypothesized that students in these clusters would report more use of strategies promoting task focusing and regaining task focusing. In contrast, we hypothesized that students in Clusters 1, 3, and 4 might select strategies oriented toward preserving their sense of well-being including, perhaps, some strategies for regaining task focusing, like tension reduction and emotion-focusing processes. Finally, we felt confident we would find higher rates of achievement (as evidenced by standardized scores, rank, and grade point average) in Clusters 2 and 5. This is because students in these clusters generally perceived tests as helping them to accomplish their goals, and they felt more or less in control of tests.

A correlation matrix of all of the variables included in Phase 3 is presented in Table 4. Findings from the ANOVAs are presented in Table 5 and Figure 4. Several general trends emerged. First, in general, clusters did appear to have distinct patterns of anxiety- and emotion-regulation strategies. In many cases, at least three different levels (i.e., high, moderate, low) emerged. This was the case for test anxiety, wishful thinking, and some of the academic achievement data. In some cases, statistically significant differences were found across four levels, for example, in the case of task-focused and importance-reappraisal strategies. Second, although we did find some differences in the achievement data, particularly in our ability to distinguish between the higher achieving groups (Clusters 2 and 5) and the lower achieving groups (Clusters 1 and 3), all of the students in our sample tended to be academically talented. In other words, at the end of their first semester in college, the average grade for each group was right around a B.

Several of our hypotheses about cluster differences were confirmed. In the following sections, we review our hypotheses as they relate to the data in Table 5 and Figure 4 and describe the ways in which students' deployment of strategies may be, in part, a reflection of their appraisals about tests.

*Cluster 1: Tests out of control.* We hypothesized that students in this cluster would report experiencing anxiety during tests and would evidence active coping but not coping oriented toward managing the problems of the test. In other words, we expected to

Figure 3. Final pooled sample five-cluster solution. Clusters were renamed when graphed to align with the clusters identified in Phase 1 of the analysis. To assist with comparison, scores on the four cognitive appraisal scales were converted to standardized scores. Note that higher scores on the Learning and Study Strategies Inventory Test Anxiety scale reflect lower rates of test anxiety.

find evidence suggesting that students in this cluster were on a well-being path. Specifically, we found that students in this cluster reported some of the highest anxiety during tests. When faced with problems during testing, students in this cluster reported lower rates of task-focusing and regaining-task-focusing regulation strategies paired with the highest rates of emotion-focusing strategies.<sup>3</sup> Thus, although they reported some of the highest levels of goal relevance and reported moderate levels of goal congruence, when faced with problems during tests, these students used the fewest strategies to manage the task and their emotions. These findings corroborate both the control-value and dual-processing theories of emotion. Finally, consistent with Linnenbrink et al. (1999; Linnenbrink & Pintrich, 2002), for students in this cluster, experiencing unpleasant emotions (i.e., anxiety) during tests was related to students' use of more emotion-focused strategies. In addition, when examining the achievement data, we noted that this group evidenced some of the lowest scores on standardized and college achievement measures.

**Cluster 2: Well prepared for challenges.** We hypothesized that students in this cluster would report lower levels of anxiety, would evidence patterns of regulation oriented toward growth (Boekaerts, 2007), and would have higher levels of achievement. Not surprisingly, students in Cluster 2 reported some of the lowest levels of test anxiety paired with reports of some of the highest standardized scores and college achievement. As hypothesized, the students in this cluster appeared to react coolly and calmly to test problems by deploying strategies oriented toward growth. This is consistent

with the control-value (Pekrun et al., 2007) theory of emotions, which states that students who perceive themselves as in control are more likely to select task-oriented strategies. When faced with problems during a test, students in this cluster reported some of the highest rates of task-focused strategy use paired with moderate rates of regaining-task-focusing strategies and lower rates of emotion-focused strategies.

**Cluster 3: Feeling hopeless.** As with Cluster 1, we hypothesized that students in this cluster would report experiencing anxiety during tests and would evidence active coping but not coping oriented toward managing the problems of the test. As hypothesized, students in this cluster evidenced some of the highest reports of anxiety during tests. Moreover, students in this cluster reported the lowest levels of task-focusing or tension-reduction strategies. Instead, students in this cluster appeared to rely on distancing strategies, reporting some of the highest levels of importance reappraisal and wishful thinking. In line with Boekaerts's (2007) dual-processing theory, we believe students in this cluster, when faced with challenges on tests, may have chosen to engage in self-preservation strategies by distancing themselves psychologically from the test. When looking at achievement data, it may be hard to think of students with a B average as having more chronic problems during tests; however, it is important to remember that

<sup>3</sup> Note that higher scores on the Learning and Study Strategies Inventory Test Anxiety scale reflect lower rates of test anxiety.

*Note.* Tukey's post hoc tests are denoted by numbered subscripts in the table. When interpreting the post hoc tests, it is noted that lower numbers (e.g., 1) report lower mean scores for a given variable than higher numbers (e.g., 4). Also, clusters with the same number were not statistically different; however, clusters with different numbers were statistically different (see Table 4). SAT = Scholastic Aptitude Test; GPA = grade point average.

<sup>a</sup> According to the scoring of the Learning and Study Strategies Inventory, low scores on anxiety are indicative of high test anxiety.

Figure 4. Patterns of anxiety and emotion-regulation strategies for the final, five-cluster sample. To assist with comparison, scores on the test anxiety and the five emotion-regulation strategy scales were converted to standardized scores. Note that higher scores on the Learning and Study Strategies Inventory Test Anxiety scale reflect lower rates of test anxiety.

these problems would be defined by the students' standards and goals. Thus, we speculate that that students in this cluster may not be achieving/performing to their standards.

*Cluster 4: Keeping tests in perspective.* This was, perhaps, the most challenging cluster for which to hypothesize differences. Because students in this cluster reported the lowest levels of goal importance and goal congruence, we hypothesized that students in this cluster would report some of the lowest levels of anxiety during tests. Consistent with appraisal theory, students in this cluster reported somewhat lower, but not the lowest, levels of anxiety during tests. However, because of lower reports of control (both agency and testing problem efficacy), we hypothesized that when faced with problems during tests, students would evidence a well-being pattern of regulation; that is, fewer reports of task-focusing regulation and higher reports of emotion-focusing strategies. Of interest, we found that students in this cluster deployed an unusual set of emotion-regulation processes, pairing moderate-to-high task-focusing strategies with some of the highest rates of importance reappraisal. Are these students oriented toward growth or well-being? Our data are a bit inconclusive. Although students in this cluster appear to have deployed strategies to manage the task of the test, they also reported that they concurrently chose to psychologically distance themselves by reappraising the importance of the test while taking the test. Although importance reappraisal during the test may have served to regulate the experience of anxiety, it may have some hidden consequences because they directed their attention away from what they could do to better

prepare for their next test. In future studies, researchers may want to examine the extent to which students in this cluster engage in procrastination strategies. In other words, to what extent are they deemphasizing the importance of the test prior to the testing situation, and how might that ultimately affect their test preparation practices (Kondo, 1997)? On the other hand, it may be that students in this cluster have different standards or goals that do not predispose them toward anxiety during tests. Although students in this cluster did not evidence the highest achievement, they also did not evidence the lowest achievement. Thus, perhaps students in this cluster merely go with the flow and avoid succumbing to the pressures of external evaluation.

*Cluster 5: Bracing for the worst.* Similar to Cluster 2, students in Cluster 5 evidenced patterns of regulation oriented toward growth (Boekaerts, 2007) and higher levels of achievement. We were uncertain about the extent to which students in this cluster would report experiencing anxiety. Of interest, students in this cluster reported lower, though not the lowest, levels of anxiety during tests. Moreover, they reported some of the lowest rates of distancing behaviors—that is, importance reappraisal and wishful thinking. When faced with problems during the test, these students deployed strategies designed to focus them on the problem of the test and their emotions (task focusing and tension reduction). These findings confirm all three theories: that when faced with problems during tests, and some anxiety, students activate strategies oriented toward growth. How do we then make sense of the finding that students in this cluster concurrently reported some of

the highest levels of self-blame? Similar to students in Cluster 2, we believe that this highly differentiated pattern of regulation, combined with students' appraisals and their higher scores on the SAT, suggest that problems during tests may actually have been somewhat rare. On the one hand, engaging in self-blame during tests may reflect a strategy of bracing for the worst (Shepperd, Findley-Klein, Kwavnick, Walker, & Perez, 2000; Taylor & Shepperd, 1998). Specifically, Taylor and Shepperd (1998) and Shepperd et al. (2000) argued that when managing emotions, students may engage in a tactic where they brace for the worst by blaming themselves. Whereas self-blame may be an emotion-focused strategy for students in Cluster 1, orienting them away from tests, self-blame may serve an activating, growth-oriented purpose for student in Cluster 5. This strategy may work for them because, in the end, the problems were minimal, and they experienced relief that they did better than they had anticipated. Moreover, their attention on what they struggled with during the test, may orient them toward making adaptive changes in their test preparation in the future. On the other hand, higher reports of self-blame may evidence a very low threshold for experiencing challenge during tests (Boekaerts, 2007). In the future, researchers may want to examine what happens when actual problems do arise during tests and students do feel anxious. We believe that students in this group may study hard and prepare for their exams but that they may tend to feel blindsided by difficulties on tests. When interpreting this cluster, we were reminded of a participant in an earlier interview project we completed (Davis et al., 1999).

For students like Jennifer, blaming herself and her preparation only worked to increase her anxiety (see also Kondo, 1997). "I lose my self-confidence by berating myself thinking, 'You know, I should have studied harder for the material. I should have looked it over more.' " This is because she already perceived herself as working very hard to prepare for the exam. Likewise, when I asked Marie what she wanted her professors to know about test anxiety, she pleaded, "Telling [students who feel anxious] to study harder does not make their problem *not* real." (Davis et al., 1999, p. 16)

Does the benefit of blaming oneself during the exam outweigh the cost of the anxiety it may produce? Though test anxiety may be less frequent, we wondered, for this group of students, whether anxiety may feel psychologically debilitating—even if faculty cannot see evidence of this debilitation in their actual achievement. Moreover, these students appear to be doing everything right, according to the appraisal and coping literature, but it may not be working for them. For students in this group, learning to put the test in perspective with their actual achievement, to engage in importance reappraisal during the test, may help them to manage anxiety that feels overwhelming.

### Implications for Theory and Practice

The purpose of this project was to explore whether there are different types of undergraduate test takers. Specifically, we were interested in examining patterns of students' appraisals about tests and patterns of coping with problems during tests. To accomplish this task, we surveyed a large sample of incoming undergraduates at a large Southwestern university and identified—across two independent samples—five unique groups, or clusters, of students that shared similar ways of approaching tests.

Findings from this study have important theoretical implications for all four of the theories of emotions in education described earlier. With regard to circumplex theory of emotions (Barrett, 2006; Linnenbrink, 2007; Russell, & Barrett, 1999), our findings may clarify why the experience of unpleasant, activating emotions like anxiety may not always lead to enhanced performance. Specifically, findings from Clusters 2, 4, and 5 reveal that when faced with problems and anxiety during tests, the students in these clusters may be activating different strategies, which may in turn have different implications for their performance. For example, when faced with problems during tests, students in Cluster 5 (bracing for the worst) reported a highly differentiated pattern of regulation drawing from task-focused processes, regaining task focus, and emotion-focused processes. Specifically, when students in this cluster activated task-focusing and self-blame strategies, it may have been to focus their attention toward elements of that test that they missed during preparation. In the short term, this strategy may have resulted in heightened anxiety during the test; however, this short-term cost may have been outweighed by the long-term benefit of increasing students' concentration and attention to detail and, in turn, may have contributed to their ability to modify preparation strategies and develop needed competencies. In contrast, students in Cluster 4 (putting tests in perspective) tended to activate a different set of strategies when faced with problems during tests. These students reported a high reliance on importance reappraisal, which may indicate that their attention was being drawn away from the test. Activation of different strategies may have caused these two groups' somewhat different patterns of achievement.

With regard to Pekrun et al.'s (2007) control-value theory of achievement emotions, our findings suggest that with two dimensions of value and two dimensions of control, we were able to consistently identify five different types of test takers, who experienced differential types of cognitive engagement with the test. Moreover, in line with Pekrun et al.'s theory, students who perceived themselves as having little control over the testing situation were more likely to report higher levels of emotion-focused coping, whereas students who perceived themselves as being in control and/or students who felt confident about managing problems were more likely to report higher levels of task-focused strategy use. Our findings, however, also add to this theory by noting the co-occurrence of task-focused and emotion-focused regulation processes within a single cluster. Future studies, perhaps with qualitative methodologies, should explore what function the constellation of strategies serves for each type of test taker as well as the costs and benefits associated with each strategy (Thompson & Calkins, 1996).

With regard to Boekaert's (1993, 2007) dual-process theory, our findings appear to confirm that there are two self-regulatory pathways students may assume while taking tests. For students in Clusters 1, 3, and 4 (out of control, feeling helpless, test in perspective), problems on tests appear to have signaled to them that something was wrong, and in lieu of choosing strategies that might have refocused them on the learning goals, these students reported deploying strategies that psychologically distanced them from the test. Although these students reported that they experienced less anxiety during tests, they also appear to have engaged in strategies that may have benefited them in the short-term by preserving their sense of well-being, but had long-term conse-

quences in that they may have distanced the students from the goal of the assessment. It is important to remember that these data were drawn from students entering their first semester at college. What might be the long-term implications of using distancing strategies? Future studies may want to explore the longitudinal impact of these orientations toward test taking.

Findings from this study also have important theoretical implications for considering both the dynamic interplay of cognitive appraisals and emotion-regulation strategies (Schutz & Davis, 2000; Schutz & DeCuir, 2002; Schutz et al., 2004). First, our findings point to the complexity of the emotion-appraisal process. Traditional appraisal theory would argue that students who do not judge tests to be important should not experience anxiety during tests. This is because the primary appraisal of importance is viewed as a necessary condition for emotion to occur. However, our data suggest that students in the feeling hopeless cluster, despite reporting that tests are not important, tended to report experiencing higher levels of anxiety during test taking. These findings corroborate Boekaerts's (2007) model, which states that perceived alignment with students' goals (i.e., goal congruence) is as important as goal importance. Additionally, we wondered about the extent to which students truly see a distinction between goal relevance and goal congruence. Although appraisal theory would suggest that these two appraisals are distinct, our findings suggest that, in general, students who reported that tests were relevant to their goals also tended to report that their test outcomes were goal congruent (see Table 4). In future studies, researchers may want to examine the extent to which, within the test-taking context, these appraisals of tests are truly unique.

Second, our findings point to the complex nature of coping strategies—specifically how one set of strategies viewed as unfavorable in the literature (i.e., self-blame) might work well for a particular group of students (e.g., those in the tests in perspective cluster). This strategy is conceptualized as emotion focused and, therefore, as a less adaptive coping strategy, because it draws students' attention and emotional resources away from the task at hand. In future studies, researchers may want to explore how students use self-blame as a way of focusing their attention (Gross & Munoz, 1995; Gross & Thompson, 2007). Could it be that self-blame means different things for different types of students? Indeed, findings from our earlier qualitative work (Davis et al., 1999) suggested that some high-achieving students tended to use self-blame in a more task-focusing way. In other words, blaming themselves for missing an item helped them to refocus their efforts for the current as well as the next test. These students' language and use of self-blame challenges the ways in which researchers have traditionally conceptualized that form of coping. Thus, additional qualitative work, attempting to identify students from each cluster for interviewing, might help researchers understand the ways in which students understand different strategies for coping with tests.

Our findings could make a significant practical contribution to the field of undergraduate student services (Tuckman, 2007). Our findings suggest that there is no single type of test taker—and that helping students to learn to manage test taking may require a more personalized approach. We hope our findings provide some practical information for faculty and instructors of undergraduate students, which can be used to help students with less adaptive

patterns of appraisals or emotion-regulation strategies to modify their approach to taking tests. Moreover, our findings may assist faculty and instructors in tailoring their feedback to fit the students they are interacting with. We hope, in particular, that our findings will help faculty and instructors to hear students when they say they struggle with anxiety during tests. For some instructors, this may mean noting that counseling students on the importance of test taking, test prep, and the consequences of test scores and grades would be an ineffective strategy for several of our clusters who may already overemphasize the importance of test scores (i.e., bracing for the worst). Moreover, educating students to engage in task-focusing and regaining-task-focusing strategies may cause some students to feel frustrated and misunderstood (e.g., students in the bracing for the worst cluster, who are already engaging in high levels of task-focused and regaining task-focused behavior). Instead, our data suggest that students' prior beliefs about test taking need to first be brought to the forefront. Some students may need to re-evaluate the extent to which tests are important to their lives, which may help students who undervalue tests (test in perspective cluster) and those who overvalue tests (bracing for the worst cluster) to consider the role that tests really play in their life goals. Moreover, careful counseling in course selection, to match challenge level with ability and to identify instructors who will work closely with students, may be the necessary first step in creating opportunities for mastery experiences for students who feel hopeless.

It is important to keep in mind that the study of emotion in educational settings is challenging. For this study, we used cross-sectional, self-report data collected to measure trait-type emotion and emotional regulation processes. In other words, in collecting the data, we asked our participants to think about testing and what they do during the testing process in general; therefore, our data were not tied to a specific test. Thus, although the data provide us with valuable insight into what might be considered trait-type processes during testing, research tied to a particular test (e.g., state emotion and emotional regulation), research that is more longitudinal in nature (e.g., following how emotions emerge and potentially change during the course of a particular test), and research that uses data-collection methods that potentially go beyond self-report methods (e.g., galvanic skin response) should be conducted.

As such, future research should examine the extent to which our five-cluster solution replicates in other populations of college students. Given the large sample size and the high hit rates across samples, we feel confident that these clusters are likely to appear in other samples. However, college students represent a relatively academically homogeneous population (those with high enough achievement to be admitted into college) compared with the larger population of students in public high schools. Thus, future studies should examine whether additional approaches to taking tests are used by lower achieving or more academically diverse populations of students. Likewise, future studies should examine the stability, throughout students' academic careers, and the validity, in other populations of students, of the five-cluster solution. Although we were successful in identifying the clusters across two independent samples, our challenges in having a clean cross-classification lead us to be hesitant to talk about the utility of the ERT as a diagnostic tool. On the other hand, challenges with cross-classification could have been an artifact of sample-specific characteristics. Future

studies should further examine the external validity of the solution, including examining whether the five-cluster solution can be distinguished with external indicators, such as first-year college students' expectations about college, their learning strategies, and their procrastination strategies (Tuckman, 2005) used in high school. This may help to illuminate whether the ERT could be scored, with our prediction rule, by an academic counselor to help classify students who may be academically at risk and to tailor interventions designed to both reduce anxiety and improve performance. Finally, it is important to remember that researchers studying emotion regulation have argued that task-focused strategies refer not only to the deployment of attention, but also to qualitatively different ways of processing information and solving problems. In future studies, researchers may want to elaborate on Schutz and colleagues' (Schutz & Davis, 2000; Schutz et al., 2004, in press) concept of task-focused processes to examine the ways in which different clusters of students solve the problem of tests in qualitatively different ways.

# Confidence and Cognitive Test Performance

Lazar Stankov and Jihyun Lee  
Educational Testing Service

This article examines the nature of confidence in relation to abilities, personality, and metacognition. Confidence scores were collected during the administration of Reading and Listening sections of the Test of English as a Foreign Language Internet-Based Test (TOEFL iBT) to 824 native speakers of English. Those confidence scores were correlated with performance accuracy scores from the TOEFL iBT and SAT, high school grade point averages (HS-GPA), and measures of personality and metacognition. The results of factor analyses indicate that confidence is a separate psychological trait, somewhere between ability and personality. The findings also suggest that confidence is related to, but separate from, metacognition. Gender and ethnic differences in confidence are also reported, with men and African Americans showing higher overconfidence bias than women and Whites or Hispanics, respectively. Finally, the data show small incremental validity of the confidence scores above and beyond the accuracy scores in predicting performance on the TOEFL iBT as a whole, the Writing and Speaking sections of the TOEFL iBT, and a test of numeracy. Confidence does not show incremental validity for the SAT and HS-GPA.

**Keywords:** confidence, overconfidence bias, metacognition, self-monitoring

Psychologists in the field of decision-making and education inspired the work on confidence by questioning whether those who know more also know more about how much they know. *Know* refers to performance accuracy, and *knowing how much they know* relates to confidence (Lichtenstein & Fischhoff, 1977). Two important theoretical approaches have been dominant in the study of confidence within the decision-making tradition: the ecological approach (Gigerenzer, Hoffrage, & Kleinbolting, 1991) and the heuristics and biases approach (Kahneman, Slovic, & Tversky, 1982). According to the ecological approach, the discrepancy between what we know and knowing how much we know can be explained in terms of the choice of difficult and “tricky” items for use in cognitive tests. These are the items for which a person does not know the correct answer and chooses to use the available cues to answer the question. These cues may be misleading. Thus, for the advocates of the ecological (sometimes also referred to as Brunswikian; see Juslin & Olsson, 1997) position, the sources of miscalibration reside outside the individual.

The heuristics and biases approach, on the other hand, attributes miscalibration to the sources from within the individual. This latter approach is sometimes called Thurstonian and is linked to the “error” model proposed by Soll (1996). According to the error model, miscalibration is due to participants’ inconsistency in forming subjective feelings of confidence and/or limited experience with the environment. This random error interacts with stimulus structure and may lead to overconfidence. Dougherty (2001) pro-

posed an integration of the ecological and error models using a modification of Hintzman’s (1988) multiple-trace memory model. This latter model predicts that miscalibration (i.e., overconfidence bias) should decrease both as a function of experience and as a function of encoding quality. Assuming that people with higher cognitive ability have more experience and better encoding quality, Dougherty’s (2001) model can be interpreted to mean that people with higher cognitive ability (or IQ) will show lower overconfidence bias.

Within the area of education, the same question is asked under the rubric of metacognition (Kleitman & Stankov, 2001; Schraw & Dennison, 1994; Stankov, 2000; Tobias & Everson, 2000, 2002). The approach of the present article has its roots in educational testing tradition, and theoretically it is Thurstonian in spirit. In our view, internally located sources of error consist of a random part that is suggested by Soll (1996) and systematic and reliable, i.e., nonrandom, individual differences in confidence. This confidence trait can play an important part in the explanations of miscalibration.

Our primary focus in this article is on the nature of confidence and to a lesser degree on the discrepancy between measures of confidence and accuracy of performance. Our aim is to demonstrate that confidence can be measured reliably and that it is a psychological trait, conceptually similar to personality and ability traits. At the group level of analysis, we examine gender and ethnic differences in performance accuracy, confidence, and overconfidence bias to highlight the potential usefulness of these measures for our understanding of behavior. The primary emphasis, however, is on individual differences in confidence, because, as we point out in a later section of this article, there are concerns about the measurement properties of overconfidence bias scores.

## Individual Differences in Confidence

Interest in confidence has a long history in psychology. Psychological studies of confidence started with the work of Fullerton

and Cattell (1882). Trow (1923) and Festinger (1943a, 1943b), among others, reported further significant work. Classical psychophysicists routinely collected three bits of information in their studies of threshold performance: accuracy, speed, and confidence. More recent studies in this area were reviewed by Vickers (1979) and Baranski and Petrusic (1999). Confidence in psychophysics is often linked to speed of providing an answer, but more complex cognitive tasks point to a relative independence of confidence and speed measures (see Stankov, 2000).

Much of the work in both decision-making and psychophysics has been experimental rather than differential in nature. It was only in the late 1990s that systematic individual differences were seriously considered as more than a part of error in the decision-making process. There is already a substantial amount of data showing individual differences in confidence ratings (Pallier et al., 2002; Schraw & Dennison, 1994; Stankov, 1998, 1999; Stankov & Crawford, 1996, 1997; Stanovich, 1999). From the individual differences point of view, confidence is a disposition (i.e., a systematic tendency that leads one to act in a particular way because it reflects a belief, a faith in oneself). Those scoring high on it can be described as decisive, firm, and resolute. Those scoring low, on the other hand, are doubtful of their capacity. Stankov (1999) has placed confidence in the no man's land between personality and abilities. Along with other dispositional measures, such as those of typical intellectual engagement, various self constructs, outlooks, and perhaps emotional intelligence, the essence of confidence cannot be reduced to either ability or personality constructs. Its advantage over most of these other constructs is the presence of a reality check in that confidence can be compared to the actual cognitive performance. This reality check operates at the subjective level (How confident am I that my answer is correct?), and, as this article discusses later, it can be assessed with an objective method (e.g., over a series of items in a test).

### The Measurement of Confidence

Accumulated evidence shows that confidence can be reliably measured in typical test-taking situations (see Crawford & Stankov, 1996). The procedure employed in the present study for assessing confidence follows Crawford and Stankov's (1996) approach. Participants are asked to give a rating (expressed in terms of percentages) immediately after responding to an item in a test, indicating how confident they are that the chosen answer for this item is correct (see Crawford & Stankov, 1996; Harvey, 1997; Keren, 1991; Stankov, 1999). Thus, these ratings directly follow the cognitive act of providing an answer. Confidence ratings for all attempted test items are averaged to give an overall confidence score. Confidence scores can be studied on their own. They can also be studied in relationship to the performance accuracy measures obtained from the same cognitive test (Kleitman & Stankov, 2001; Stankov, 2000). These are sometimes referred to as calibration studies.

In studying the relationship between confidence and accuracy on a typical cognitive test, performance accuracy scores are often converted to average percentage correct and subtracted from the average percentage confidence scores. The result is called the *bias* (or *realism*) score. There is a considerable amount of data showing overconfidence bias in cognitive tasks—that is, a pronounced

(positive) difference between confidence and accuracy scores (see Lichtenstein & Fischhoff, 1977; Lichtenstein, Fischhoff, & Phillips, 1982). Pronounced underconfidence bias has been found with some sensory tasks (Olsson & Winman, 1996). However, we use the term bias interchangeably with overconfidence bias in the present study, because all tasks employed in this study are known to display overconfidence (Stankov, 2000). Zero is often treated as an ideal value for bias scores because a good match, frequently referred to as good calibration, between the level of confidence and performance is often seen as a desirable characteristic. In this article, we do not report bias scores at the individual levels of analysis. We report only arithmetic means of bias scores (i.e., differences between the means for accuracy and confidence scores) to point out the discrepancies between subpopulations.

### Correlates of Confidence

Recent studies show that confidence is a general trait and structurally independent of other established ability and personality traits (see Blais, Thompson, & Baranski, 2005; Klayman, Soll, Gonzalez-Vallejo, & Barlas, 1999; Kleitman & Stankov, 2001; Pallier et al., 2002; Stankov, 1998, 1999, 2000; Stankov & Crawford, 1996, 1997). There are three main domains that have been conceptually and empirically related to the construct of confidence.

First, confidence scores have shown moderate correlations with measures of *cognitive abilities*—that is, a higher accuracy score is linked to a higher confidence level. The list of different cognitive tasks employed in studies of confidence to date includes measures of verbal and nonverbal reasoning (fluid intelligence, *Gf*); acculturated knowledge (crystallized intelligence, *Gc*); long-term and short-term memory; and visual, olfactory, gustatory, and auditory perceptual processes, among others. In general, the studies show that people who are more confident on one cognitive task tend to be more confident across other tasks. Although evidence indicates that correlations between performance accuracy and confidence scores from the same tests tend to average between .40 and .60 (Stankov, 2000), correlations between confidence scores from different cognitive tests have been equal to or higher than correlations between performance accuracy and confidence scores from the same tests. That suggests a general confidence factor that is separate from (yet positively related to) factors of intelligence. Confidence as a separate factor has been identified in studies of Kleitman and Stankov (2001); Pallier et al. (2002); Stankov (1998, 1999), and Stankov and Crawford (1996, 1997; see also Stanovich, 1999).

Second, confidence is sometimes treated as a *personality trait*, either on its own or as an underlying facet of broader traits (Blais, Thompson, & Baranski, 2005; Pallier et al., 2002). Consistent small correlations ( $r = .30$ ) between confidence and the openness factor from the Big Five model have been noted (Pallier et al., 2002). However, it is unclear whether this relationship with openness is mediated by cognitive ability, because both confidence and openness correlate with cognitive ability. Moreover, Blais et al. (2005) demonstrated that a broad range of cognitive styles, including the need for cognition and the desire for structure, had no effect on confidence. Conceptually, cognitive styles straddle the boundary between personality and metacognition.

Third, as mentioned in the introduction, confidence judgments are frequently interpreted as an important aspect of *metacognitive* processes. Metacognition refers to an awareness of the learning process and one's cognitive strengths and weaknesses and therefore affects confidence judgments. In the writings of Nelson and Narens (1992, 1994) on metacognition, confidence ratings are assigned a somewhat limited role—they are assumed to provide no other metainformation apart from whether to retrieve an answer or continue a cognitive search further. Consequently, these researchers are mainly concerned with investigations of the ease of learning, judgments of learning, and feeling of knowing, often neglecting unique confidence ratings. On the other hand, many researchers see confidence judgments as noteworthy topics for psychological study. For instance, Baron (2000) argued that “appropriate confidence is, in most cases, a more realistic goal than certainty” (p. 62). That is, the metacognitive ability to appraise the relevance of one's own beliefs about the available evidence (and one's own performance) is an important factor in effective decision-making. One component of metacognition, self-monitoring, refers to the awareness of the accuracy of one's answers on typical cognitive tests. Bias score can be used as a direct measure of self-monitoring (see Schraw & Dennison, 1994). Broader aspects of metacognition are frequently assessed with questionnaires. Although questionnaire measures of metacognition have shown a moderate relationship with confidence in studies by Kleitman (2003) and Kleitman and Stankov (2006), those measures also defined a separate metacognitive factor that was distinct from the confidence factor itself. In this article we ask the same question—that is, do questionnaire measures of metacognition define a different factor from measures of confidence?

### Gender and Ethnic Differences in Confidence and Bias Scores

Gender differences in confidence and bias scores have been examined extensively, but the findings are less than conclusive so far. Studies by Stankov and Crawford (1996, 1997) found no gender differences, but more recent studies by Pallier et al. (2002) and Pallier (2003) show significant gender differences in confidence, with women exhibiting lower bias scores (i.e., better calibration) on cognitive tasks. We address the gender difference issue in this article.

The evidence for possible ethnic differences in confidence has been explored only indirectly so far. Stankov and Kim (2006) found that on tests of esoteric analogies and vocabulary, foreign students seeking admission to U.S. universities tend to have overconfidence bias scores that are about twice as high as U.S. students. At present, there is no available information on whether different ethnic groups within a country show pronounced differences in confidence ratings. In the present study, we examine ethnic differences in confidence and bias scores between Whites, Hispanics, and African American participants.

### Evidence for Incremental Validity of Confidence Scores

The evidence for incremental validity of confidence scores is not available at present. The concept of incremental validity is based on the question of whether a measure can predict a criterion over and above what has been predicted by some other variable. In

other words, can confidence predict some sort of educational and job-related outcome after taking account of the accuracy of performance on the test? The focus, to date, has been on the understanding of confidence scores themselves (Kleitman & Stankov, 2006). In this study, we address the issue of their predictive validity using various measures of aptitude as criteria (i.e., self-reported SAT scores, high school grade point average [HS-GPA], numeracy test scores, Test of English as a Foreign Language [TOEFL] scores for the Writing and Speaking sections). These are all measures that are known to predict both school achievement and training and job-related performance.

Our approach to measuring confidence is to obtain accuracy and confidence scores from the same cognitive act. In showing the incremental validity of confidence scores above and beyond their yoked accuracy scores, we predict accuracy scores from cognitive measures that are not used to extract confidence scores. For example, the question is whether confidence scores that are obtained from the Reading sections in the TOEFL exam will add to the prediction of, say, HS-GPA above and beyond TOEFL Reading performance accuracy scores.<sup>1</sup> This is a stringent requirement, because performance accuracy scores from both criterion and predictor sets of measures (HS-GPA and TOEFL Reading section) are capturing the same construct—acculturated knowledge (or crystallized ability, *Gc*). The presence of incremental validity may contribute to the argument for using confidence scores in selection and guidance programs.

Schmidt and Hunter (1998) showed that only two noncognitive constructs—conscientiousness and integrity—have incremental validity beyond performance accuracy scores. In this context, even a small amount of incremental validity that can be attributed to confidence after taking account of measures of performance accuracy from the same test will be of importance.

### TOEFL Internet-Based Test (iBT) as a Measure of Verbal Comprehension Ability in Native Speakers of English

We assess confidence during the administration of a TOEFL iBT exam to native speakers of English. Although confidence expressed in each TOEFL item may be confined to participants' confidence in his or her command of English, confidence is a part of any cognitive activity that requires decision-making, not just foreign-language learning. Thus, in this study, confidence scores based on subjective judgments of the accuracy of each item in the TOEFL exam are used in the same way as any other cognitive test can be used.

The most recent version of the TOEFL exam (known as the TOEFL iBT) consists of four sections: Reading, Listening, Writing, and Speaking. The test is delivered via the Internet. Detailed analyses of the TOEFL iBT exam based on nonnative speakers of English are provided in the Educational Testing Service's technical report by Sawaki, Stricker, and Oranje (2005). As has been the case with previous versions of TOEFL, the validation process includes administration of the test to native speakers of English (see Angelis, Swinton, & Cowell, 1979; Angoff & Sharon, 1971; Johnson, 1977; Stricker, 2002). The present study is based on such

<sup>1</sup> This is just an example. We do not expect to predict HS-GPA particularly well by aspects of language proficiency captured by the TOEFL iBT.

a sample of native speakers from community colleges who took the TOEFL iBT exam. There is considerable evidence showing that TOEFL performance correlates with other cognitive tests (Stricker, 2002). With nonnative speakers of English, the Graduate Record Examination verbal reasoning score correlation is .61 with the TOEFL total score. For native speakers of English, this correlation is .64 (Stricker, 2002). This finding has led to a speculation that it may be possible to use the TOEFL exam as a proxy for the Graduate Record Examination or SAT tests under some circumstances.<sup>2</sup> Within a broad area of human cognitive abilities, TOEFL measures verbal comprehension primary ability and acculturated knowledge (*Gc*) at the second-order level.

Two sections in the TOEFL iBT exam—Reading and Listening—contain multiple-choice items, the item type that has been employed in most previous studies of confidence. A sample of these TOEFL multiple-choice items was used to collect confidence ratings in the present study. Performance accuracy scores on the TOEFL Speaking and Listening sections as well as the TOEFL total scores were also used in our study (see the Method section in this article). To check the interpretation of TOEFL accuracy scores as measures of cognitive ability and *Gc* in particular, we included in this study a numeracy test from the literacy battery developed by Kirsch et al. (2001), as well as an overclaiming test—a self-reported word knowledge measure employed in studies of overclaiming (see Paulhus & Harms, 2004).

### Goals

The purpose of this study is to examine the nature of confidence exhibited during performance on two sections (Reading and Listening) of a cognitive test, the TOEFL iBT assessment. Two issues are addressed.

First, we examine psychometric properties of confidence scores that are obtained from TOEFL iBT Reading and Listening sections—their reliability and validity. In accordance with the findings from previous studies that employed different cognitive tests, the expectation is that confidence scores from TOEFL iBT Reading and Listening tests show satisfactory reliabilities (test–retest, parallel forms, and internal consistency). Two broad classes of validity evidence for confidence scores are considered in this article.

*Construct validity* is assessed by examining the relationship of confidence scores to (a) performance accuracy scores from the Reading and Listening tests, (b) personality traits, and (c) questionnaire measures of metacognitive awareness. In accordance with previous findings with different test batteries, we hypothesize that confidence scores from Reading and Listening tests will measure a psychological trait that is different from traits from these three distinct domains. Exploratory factor analysis is used to check if a separate confidence factor, independent of accuracy and metacognitive factors, can be identified. In addition, measures of Big Five personality traits are correlated with performance accuracy and confidence scores. If confidence is indeed a trait separate from personality traits, it can be expected that correlation between confidence and personality traits would not be too high and perhaps comparable to the correlation of accuracy scores with personality traits.

*Predictive validity* of confidence measures is examined using regression analyses and correlations. Several performance accu-

racy scores are used as criterion measures: scores from TOEFL iBT Writing and Speaking sections, TOEFL iBT total scores, standardized measures of academic performance (SAT and ACT), HS-GPA, and two additional cognitive tests (numeracy and overclaiming). Although it is hypothesized that both performance accuracy and confidence scores from Reading and Listening tests are good predictors of these criteria, it is expected that confidence scores have incremental validity over and above accuracy scores for at least some criterion measures. Confidence scores are also related to another criterion measure: the amount of change in performance accuracy between two occasions of testing. It is hypothesized that people who have low confidence will change their answers between two occasions of testing to a greater extent than those with high confidence. This hypothesis implies negative correlation between confidence scores and absolute values of change scores between two occasions of testing.

Second, we explore group differences (i.e., gender and ethnic differences) on accuracy, confidence, and bias scores from Reading and Listening tests. The presence of these differences can be interpreted as additional evidence for construct validity of confidence and bias scores. In accordance with previous findings, it is expected that men show greater overconfidence bias than women. In other words, it is expected that women are better calibrated than men. With respect to hitherto unexplored ethnic differences between Whites, Blacks, and Hispanics, no definite prediction can be made. However, indirect evidence can be used to hypothesize that groups with low performance accuracy scores show higher overconfidence bias than those with high accuracy scores. Thus, ethnic groups that show lower performance accuracy are expected to show greater overconfidence bias.

## METHOD

### Participants

As mentioned above, the data for the present study were collected as a part of the validation process for TOEFL iBT. Participants were recruited for the validation study and were paid \$100 for taking part in this research. This was not a high-stakes assessment for them. To save time and effort and collect data on additional noncognitive variables, including measures of self-confidence, we decided to use the same sample of participants.

Participants ( $N = 824$ ) were recruited from two types of colleges. One group ( $N = 371$ ) came from nine 2-year community colleges.<sup>3</sup> The other group ( $N = 453$ ) came from twelve 4-year colleges, from across the United States. All participants were native speakers of English. There were 304 male and 518 female

<sup>2</sup> This suggestion is supported by the present data. For the subsamples who reported their SAT and ACT scores, the correlations are:  $r_{\text{TOEFL,SAT}} = .54$ ,  $r_{\text{TOEFL,ACT}} = .65$ ,  $r_{\text{TOEFL,HSGPA}} = .33$  (see Table 10 for the  $N$ s).

<sup>3</sup> The total  $N$  for this study was, in fact, 950. Preliminary screening of the data showed that a proportion of participants produced patterns of responses indicating careless responding (e.g., the same answer was provided for all items in a given instrument). This tendency was particularly pronounced with the instruments administered in the afternoon session, not with TOEFL iBT scores. Our criterion for excluding participants was the presence of evidence for careless responding in 3 out of 28 instruments administered in the afternoon session, some of which are used in the present report.

participants. In terms of ethnic composition, the sample consisted of Whites ( $N = 605$ ), African Americans ( $N = 112$ ), Hispanics ( $N = 60$ ), and Others ( $N = 46$ ). The mean age of the sample was 19.6 years ( $SD = 3.2$ ).

### Procedure

Participants were administered the full TOEFL iBT exam in the morning and were asked to attend another session in the afternoon on the same day. The order of TOEFL iBT subtests in the morning session was: Reading, Listening, Writing, Speaking. The data from this session were intended for validation purposes.

The afternoon session started with the repeated (untimed) test consisting of the selected Reading and Listening items with confidence ratings attached to each item (see the *Instruments* section of this article). The time interval between beginning of morning and afternoon presentation of the same tests was 4 hr, shorter than what is usually done in studies of test-retest reliability. However, it should be kept in mind that there was intensive cognitive activity (i.e., taking of Writing and Speaking tests) between the two sessions, which may have affected memory traces for the repeated items. Thus, the increase in the overall performance accuracy in the second session is expected to be relatively small. The effect of prior exposure to the same items on the confidence scores is unknown at present. One would expect some increase in confidence and improvement in its reliability but the size of these effects is hard to estimate.

After completing the Reading and Listening tests, the participants took a battery of 28 instruments. These additional instruments were a measure of cognitive ability, personality, metacognition, interests, and emotional intelligence, as well as social attitudes, values, and social norms. Noncognitive variables require less mental effort than TOEFL iBT. With a lunch break between the morning and afternoon sessions and two breaks in the afternoon session, fatigue was not deemed to have a major influence on performance. Nevertheless, the effects of fatigue on test performance cannot be discounted. Depending on participants' speed of working through the paper-and-pencil noncognitive measures, the afternoon session lasted approximately 3 hr. In this article, we only report results on the accuracy and confidence scores obtained from the repeated items on the TOEFL iBT Reading and Listening sections. The validation process for confidence scores includes the measures of cognitive ability, personality, and metacognition selected from the entire battery of 28 measures.

### Instruments

#### TOEFL iBT

TOEFL iBT (Form B) consists of four sections: Reading, Listening, Speaking, and Writing. The description of these four sections follows.

**Reading.** The Reading section has three sets of items, each associated with a common reading passage of approximately 700 words. It contains a total of 40 items (12, 14, and 14 in Sets 1, 2, and 3, respectively). The examinees are allowed to spend 60 min completing the Reading section. Thirty-seven items are four-option multiple-choice items. One item in each set is an open-ended item. The work reported in this article is based on the

multiple-choice items in the first two item sets. Thus, Reading Version 1 consisted of 11 items from the first set and Reading Version 2 consisted of 13 items from the second set. Figure 1 presents a screen capture of an item from the Reading section and confidence ratings scale associated with the item.

**Listening.** The Listening section has 34 items in six item sets, with two item sets based on conversation and four item sets based on lectures on academic topics. Each stimulus is approximately 3 min long and is followed by 5 items with four multiple-choice options. A lecture stimulus lasts 3 to 5 min, followed by 6 items. After listening to the prompts, the participants can spend up to 20 min responding to all Listening items. Given a constraint on testing time in the afternoon testing session, we selected only conversation-based Listening items (17 items). Listening Version 1 contains 11 items from two different conversations, and Listening Version 2 contains 6 items from another conversation.

**Speaking.** The Speaking section consists of six items. Two items require examinees to express opinions on familiar topics. The other four items integrate speaking with other language tasks. Two of the four integrated tasks combine listening and speaking skills, which requires examinees to listen to a short dialogue and then to talk about the content of what they heard. The remaining two are Reading/Listening/Speaking tasks, which require examinees to read a short passage, listen to a dialogue that pertains to the passage, and then speak about what they have read and heard. For each of these items, examinees are given 15–30 s to prepare and 45–60 s to respond. Examinees' responses to each item are scored on a scale of 0–4 by trained raters. The raw Speaking score is a sum of the points across all six items; thus, examinees' raw Speaking scores range from 0 to 24.

**Writing.** The Writing section includes two items, one of which is an independent writing task, and the other is a writing task integrated with a reading task. The independent writing task requires examinees to argue for an opinion on a topic. The integrated writing task requires the examinees to read a text, listen to a lecture that pertains to the topic, and then write on a specific topic that is based on what examinees have read and heard. The testing time for the Writing section is 20 to 50 min for the independent writing task and 30 min for the integrated writing task. Examinees' responses to each item are scored on a scale of 0–5 by trained raters. The raw Writing score is a sum of the points earned on the two items; thus, the raw score ranges from 0 to 10.

The raw scores from each section of TOEFL iBT are converted to scaled scores of 0 to 30. The total TOEFL iBT score is a simple sum of the four scaled scores, ranging from 0 to 120.

#### Additional Ability Measures

Two ability measures, apart from TOEFL iBT, were used in this study:

**Numeracy test.** The National Adult Literacy Survey developed by ETS contains a numeracy test to assess examinees' ability to use and manipulate numerical information in a real-world context (Kirsch et al., 2001). Seventeen items from this test were used in the present study.

**Overclaiming test.** This 45-item instrument (see Paulhus & Harms, 2004) assesses respondents' overclaiming familiarity with historical names and events, social sciences, and physical sciences. Each item is on a scale ranging from 0 (*never heard of it*) to 6

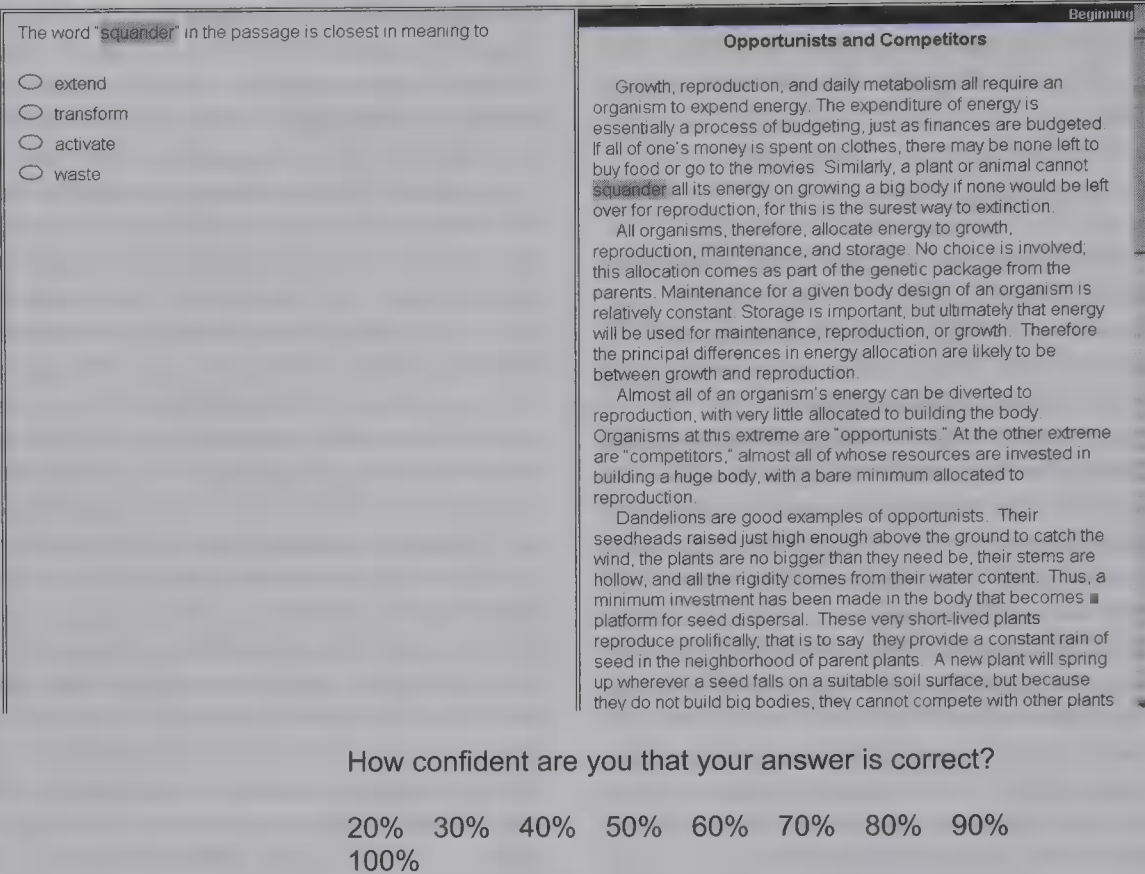

Figure 1. Screen capture of an item from the Test of English as a Foreign Language, Internet-Based Test, Form B. This item was used in a pilot study in 2006; it is not part of the test as currently administered. After providing the answer to an item, participants were asked to answer the confidence question.

(*know it very well*). Within each of three categories, 3 out of every 15 items are foils—that is, they do not actually exist. Hence, any degree of familiarity with them constitutes overclaiming. The data on overclaiming are typically analyzed by the signal detection theory (Paulhus & Harms, 2004). Signal detection analysis exploits all of the data in the calculation of separate indexes for *accuracy* and *response bias*. The best known formula for accuracy is *d'*. It assumes that an accurate individual is not the one scoring the most hits, but the one showing the best discrimination in claiming to recognize real items relative to foils. We did not employ response bias measures in this study.

Metacognitive Inventories

Three questionnaires were employed to assess metacognition.

*Metacognitive Awareness Inventory (MAI).* Ten items were chosen from the original 52 items of the MAI (Schraw & Dennison, 1994). These items showed satisfactory psychometric properties in a pilot for the present study. In the pilot study, all 52 items of MAI defined a single (general) metacognitive factor. The 10 selected items had the highest loadings on this general factor. Cronbach's alpha in this study is .76. The MAI contains questions on students' self-perceptions as learners, their strong and weak points, and their learning strategies and conditions under which they can learn most effectively.

*Memory and Reasoning Competence Inventory (MARCI).* This is a measure of self-concepts of memory and reasoning (Kleitman, 2003; Kleitman & Stankov, 2007). The inventory con-

sists of 16 items, 8 items for each component. The items assess people's perception of their reasoning and memory abilities relative either to other cognitive abilities they possess or to other people's cognitive abilities. The process of scale development is based on a model of self-concept items (Marsh & Shavelson, 1985; see also Marsh, 1986). The respondents evaluate the extent to which each statement describes them using a 6-point Likert scale ranging on a 6-point gradation from *false* (scaled at 1) to *true* (scaled at 6). Reasoning and memory items are intermixed, and separate scores for these two components are calculated. Kleitman (2003) has shown that 8 items of memory and 8 items of reasoning define two separate factors. Examples of memory items include "Compared to other intellectual abilities (i.e., attention, reasoning), my memory is good," and "My memory is above average." Examples of reasoning items include "I feel confident when solving problems that require reasoning skills," and "I can reason better than the average person." In the present study, Cronbach's alpha for the Reasoning component of MARCI is .73; for the Memory component, it is .79.

Personality Measures

For a personality measure, we used the Big Five Personality Inventory scales for Extraversion, Conscientiousness, Agreeableness, Emotional Stability, and Openness with reliability coefficients in this study of .81, .75, .75, .81, and .78 respectively. These scales are available from the International Personality Item Pool (n.d.).

Table 1  
*Arithmetic Means for Accuracy, Confidence, and Bias Scores for TOEFL iBT Reading and Listening Sections*

Test	<i>N</i>	Accuracy		Confidence <i>M</i>	Bias <i>M</i>
		<i>M</i> ( <i>SD</i> )	% correct		
1st presentation: TOEFL iBT					
Reading 1	11	8.55 (2.12)	78.78	—	—
Reading 2	13	9.38 (2.58)	72.15	—	—
Listening 1	11	8.84 (2.06)	80.36	—	—
Listening 2	6	4.94 (1.17)	82.33	—	—
2nd presentation: TOEFL iBT with confidence scale					
Reading 1	11	8.78 (2.19)	79.82	88.47	8.65
Reading 2	13	9.44 (2.56)	72.54	87.37	14.83
Listening 1	11	8.98 (2.05)	81.64	87.21	5.57
Listening 2	6	5.01 (1.19)	85.00	90.48	5.48

*Note.* *N* = 824. Dashes indicate that information was not available. TOEFL = Test of English as a Foreign Language; iBT = Internet-Based Test.

### Outcome Measures

Participants were also asked to provide their scores on standardized tests (either the SAT or ACT) and their HS-GPA. These are self-reported scores that have not been checked for accuracy.

## RESULTS

### Descriptive Statistics on the Accuracy and Confidence Scores

Descriptive statistics for accuracy and confidence scores are provided in Table 1. The information about the TOEFL iBT first presentation in Table 1 was obtained from the selected items during the full operational TOEFL iBT testing session in the morning. The information about the second presentation was obtained from the same items given in the afternoon session, which included participant-selected confidence ratings for each item. Raw scores were transformed into percentage-correct scores by dividing the raw score by the number of items in the test and multiplying by 100. The means column for confidence in Table 1 shows the average confidence score across the items in each scale. The bias column in Table 1 presents the difference between the means for confidence and the percentage-correct scores.

Four observations are noteworthy in Table 1. First, there are remarkably small differences in the mean performance between the morning and afternoon sessions. What is surprising is that the absence of time restriction in the afternoon session did not affect performance to any significant degree, at least at the group-mean level. Second, the Reading section was more difficult than the Listening, although both were somewhat easy as expected from the sample of native English speakers—the average difficulty levels range between 72% and 85%. The effect of a test's easiness on confidence scores is to reduce the number of low confidence ratings in the test. However, the work of Stankov and Crawford (1996, 1997) and Kleitman and Stankov (2001, 2007) suggests that test difficulty does not affect the nature of the relationship between accuracy and confidence. Third, the mean variations across four sets of tasks (i.e., Reading 1 and 2 and Listening 1 and 2) were

more salient in the accuracy scores than the confidence scores. In other words, the participants' confidence scores were more constant throughout the different tasks. Fourth, Reading 2 shows an unusually high bias score in the present data.<sup>4</sup> Previous studies with cognitive tests indicated that bias scores greater than 10% could be treated as nonnegligible (Kleitman & Stankov, 2001; Stankov & Crawford, 1996, 1997).

### Reliabilities of the Accuracy and Confidence Scores

Three types of reliability coefficients are presented in Table 2: (a) Cronbach's alphas for the accuracy and confidence scores, (b) parallel form (i.e., correlations between the accuracy scores on Versions 1 and 2 for the Reading and Listening sections), and (c) test-retest reliabilities (i.e., correlations between the accuracy scores from the two administrations).

The reliability coefficients for both the accuracy and the confidence scores are all at an acceptable level for research purposes, except for Listening 2, which contains only six items. It is noteworthy that reliabilities of the confidence scores are consistently high across different tasks and different versions. The confidence scores show higher reliabilities than the accuracy scores.

### Effect of Confidence on Changes in Accuracy Scores From Test to Retest

This section explores the cause of less than perfect correlations in the accuracy scores between the two testing sessions as a function of participants' confidence levels. We obtained absolute change scores from the differences in the accuracy scores between the morning and afternoon sessions. The absolute change scores indicate the amount of change irrespective of whether there was a

<sup>4</sup> One of the items in the Reading Version 2 was based on a partial scoring method—i.e., instead of 0, 1 scoring, a 0, 1, 2, 4 scoring key was employed. When we removed this item from the analyses, the overall bias score for Reading Version 2 was reduced by 2.94 percentage points, closer to the borderline value for noteworthy bias scores.

Table 2  
Reliabilities for TOEFL iBT Reading and Listening Scores With and Without Confidence Scale

Test	N	$\alpha$	Accuracy		Confidence $\alpha$
			Parallel	Test-retest	
1st presentation: TOEFL iBT					
Reading 1	11	.73	—	—	—
Reading 2	13	.79	.70	—	—
Listening 1	11	.75	—	—	—
Listening 2	6	.62	.55	—	—
2nd presentation: TOEFL iBT with confidence scale					
Reading 1	11	.82	—	.85	.91
Reading 2	13	.79	.72	.78	.94
Listening 1	11	.78	—	.71	.94
Listening 2	6	.72	.59	.68	.90

Note. Dashes indicate that information was not available. TOEFL = Test of English as a Foreign Language; iBT = Internet-Based Test.

reduction or increase in accuracy scores between these two sessions. The arithmetic means for the absolute change scores are shown in Table 3. Comparison between the means for the absolute change scores shows that changes occurred more frequently on the Reading section, which is more difficult, than on the Listening section. On the other hand, the correlation between Listening and Reading absolute change scores is somewhat high ( $r = .60$ ), indicating that the tendency for participants' scores to change between the two testing sessions is consistent across the two sections. The correlations between the absolute change scores and the confidence scores are negative, with the correlations in the upper .20s—more confident people tend to have lower absolute change scores. Thus, confidence is possibly one source of unreliability in the accuracy test scores, reflected in test-retest correlations. This may be because low confidence and guessing go hand in hand, and guessing, of course, lowers a test's reliability. Another interpretation of this finding is in terms of predictive validity—confidence scores may be predictors of repeated taking of high-stakes tests. People who show low confidence may be more prepared than those with high confidence to take a test over and over in the hope of improving their scores.

Table 3  
Pearson Product-Moment Correlations Between Absolute Change Scores Between Test and Retest and Confidence Scores on TOEFL iBT Reading and Listening Sections

Variable	Absolute change scores		Confidence scores	
	Reading	Listening	Reading	Listening
Absolute change scores				
Reading	—			
Listening	.60	—		
Confidence scores				
Reading	-.29	-.27	—	
Listening	-.18	-.26	.77	—
M (SD)	2.22 (3.02)	1.58 (2.20)		

Note. TOEFL = Test of English as a Foreign Language; iBT = Internet-Based Test.

### Factor Analyses of the Confidence Scores

This section explores whether the confidence factor stands separate from cognitive abilities and metacognition. Two analyses were carried out. The first factor analysis employed four sections of the TOEFL iBT exam that were administered in the afternoon session. This analysis was based on eight variables—accuracy and confidence scores from four measures (Listening 1 & 2 and Reading 1 & 2). The second analysis included the first battery of sections as well as other cognitive ability tests—numeracy and overclaiming  $d'$ —and the questionnaire measures of metacognition (MARCI measures of reasoning and memory, and MAI). The reason for carrying out two factor analyses is our assumption that four accuracy and four confidence scores derived from two tests that are purported to measure essentially the same construct (i.e., language proficiency) are conceptually at the same level as other cognitive ability tests employed in the second analysis. In other words, Versions 1 and 2 of the same test are parallel forms of estimates and their sum corresponds to a single, say, numeracy score.

#### First Factor Analysis

Table 4 presents correlations between the accuracy and confidence scores from the two versions of the TOEFL iBT Reading and Listening sections. All correlations are moderately high and positive. Several observations are noteworthy. First, the confidence scores correlate higher among themselves than do the accuracy scores. Second, for both accuracy and confidence scores, the correlations between the two sections (i.e., between Versions 1 and 2 of the same test) are higher than the correlations between Reading and Listening sections. Third, correlations between the accuracy and confidence scores from the same task range from .445 to .605. They are higher than the correlations between accuracy and confidence scores from the different versions of the same tasks (ranging from .358 to .574). Fourth, there are somewhat stronger associations between Reading accuracy and confidence scores (ranging from .469 to .605) than between Listening accuracy and confidence scores (ranging from .358 to .490).

Tables 5 and 6 provide a factor pattern matrix on the accuracy and confidence scores. The exploratory factor solution was ob-

Table 4  
Pearson Product-Moment Correlations Between Accuracy and Confidence Scores From TOEFL iBT

Variable	Accuracy scores				Confidence scores			
	Reading 1	Reading 2	Listening 1	Listening 2	Reading 1	Reading 2	Listening 1	Listening 2
Accuracy scores								
Reading 1	—							
Reading 2	.781	—						
Listening 1	.552	.595	—					
Listening 2	.569	.616	.684	—				
Confidence scores								
Reading 1	.605	.574	.431	.499	—			
Reading 2	.469	.519	.366	.450	.824	—		
Listening 1	.350	.360	.445	.490	.704	.768	—	
Listening 2	.282	.291	.358	.480	.629	.717	.822	—

Note. TOEFL = Test of English as a Foreign Language; iBT = Internet-Based Test.

tained by applying the root-one criterion and using the maximum likelihood estimation procedure followed by promax rotation. It clearly shows that two factors—verbal comprehension (i.e., accuracy scores from the TOEFL iBT Reading and Listening sections) and confidence—exist in these data. These two factors account for 77.44% of total variance of the eight-test battery. Factor intercorrelation (.578) is within expectations because typical correlations between confidence and performance factors range between .40 and .60.

### Second Factor Analysis

Table 7 shows correlations between the accuracy scores on cognitive ability tests (TOEFL iBT Reading and Listening sections, Versions 1 and 2 combined, the numeracy and overclaiming  $d'$  tests), the metacognitive measures (memory inventory, reasoning inventory, and metacognitive awareness inventory), and the confidence scores from TOEFL iBT Reading and Listening sections, Versions 1 and 2 combined. All the correlations in Table 7 are positive and moderate in size (except for essentially zero correlation between metacognitive awareness and overclaiming  $d'$

scores). As expected, the correlations in Table 7 are lower overall than those presented in Table 4.

Tables 8 and 9 show the factor pattern matrix and the factor correlation matrix based on the correlation matrix presented in Table 7. We report maximum likelihood solution followed by promax rotation. Using the root-one criterion, three factors were extracted. These factors account for 65% of the total variance. They are:

*Acculturated knowledge (Gc).* The accuracy scores from all four tests of cognitive abilities load on this factor. Although three of the four tests that load on this first factor involve verbal abilities, loading from the numeracy test indicates that the processes captured by this factor are somewhat broader than verbal comprehension, perhaps tapping crystallized abilities. Reading confidence also has a small loading on this factor.

*Confidence.* The confidence scores from the TOEFL iBT Reading and Listening sections load on this factor. Unfortunately, this is a doublet due to the absence of other measures of confidence in this study. However, previous work has shown that the confidence factor can be reliably extracted from a larger number of cognitive tasks (see Kleitman & Stankov, 2001; Pallier et al., 2002; Stankov, 1998, 1999, 2000; Stankov & Crawford, 1996, 1997).

*Metacognition.* All three questionnaire measures of metacognitive processes load on this factor.

The correlation between the acculturated knowledge ( $Gc$ ) and confidence factors is moderate in size ( $r = .552$ ), about the same as the one reported between verbal comprehension and confidence in Table 5. The metacognitive factor shows lower correlations with both  $Gc$  and confidence factors ( $r = .379$  and  $.317$ , respectively).

Table 5  
Exploratory Factor Analysis of the Correlations Between Accuracy and Confidence Scores

Variable	Factor	
	Confidence	Verbal comprehension
Accuracy scores		
Reading 1		.918
Reading 2		.967
Listening 1		.598
Listening 2	.215	.570
Confidence scores		
Reading 1	.593	.358
Reading 2	.753	
Listening 1	.962	
Listening 2	.958	

Note. Empty cells indicate that factor loading is lower than .200.

*Correlations Between TOEFL iBT Reading and Listening Confidence Scores and Accuracy Scores From TOEFL iBT, SAT, ACT, and HS-GPA*

Table 10 presents correlations between a composite confidence score (i.e., the sum of the confidence scores from the TOEFL iBT Listening and Reading sections) and other cognitive test scores (i.e., total TOEFL iBT, SAT, and ACT) and HS-GPA.

As expected, correlations between confidence scores and scores from the TOEFL iBT Reading (.499) and Listening (.539) sections are higher than correlations between confidence scores and scores from the TOEFL iBT Speaking (.338) and Writing (.414) sections. Confidence scores correlate moderately with total TOEFL iBT scores ( $r = .553$ ), which is comparable to the correlations between the confidence and accuracy factors in Tables 6 and 9. Less than half of participants provided self-reported SAT and ACT scores. For these subsamples of participants, the correlation of self-

reported SAT and ACT scores with confidence scores is rather low ( $r = .271$  and  $.238$ ). Self-reported HS-GPA shows the lowest correlation with confidence scores ( $r = .159$ ).

*Correlations Between Confidence Scores and Big Five Personality Traits*

Table 11 presents correlations between Big Five personality dimensions and total TOEFL iBT and composite confidence scores. The accuracy and confidence scores based on the TOEFL iBT exam show a moderate relationship with openness. This finding is in agreement with the findings of Pallier et al. (2002). We obtained somewhat higher correlations of agreeableness with both the accuracy and confidence scores than previous studies have reported (Kleitman & Stankov, 2007; Pallier et al., 2002). Generally speaking, the pattern of personality traits' correlations is similar for the accuracy and confidence scores. What is particularly noteworthy is that personality traits show slightly higher average correlations with the accuracy scores than with the confidence scores. In previous studies, the construct of confidence has been linked to personality traits more often than any other constructs (see Blais, Thompson, & Baranski, 2005; Klayman et al., 1999; Kleitman & Stankov, 2001; Pallier et al., 2002). Our data in this study suggest that personality traits have the same relationship to cognitive abilities as they do to confidence, or slightly closer.

Summary of Structural Findings

We have shown that confidence can be measured reliably. Our findings suggest that although moderately correlated with cogni-

Metacognition	.379	.317	—

tive abilities, metacognition, and personality traits, a confidence factor is distinct and cannot be reduced to either ability or personality domains. There is nothing in the present data that challenges the conclusion that confidence is indeed a separate trait.

### Group Differences in Confidence: Gender, Ethnicity, and College Type

Table 12 displays the mean levels of the accuracy, confidence, and bias scores for the TOEFL iBT Reading and Listening sections for the total number of participants and male and female participants. Positive signs for mean bias scores indicate overconfidence at the group level of analysis. Men tend to show greater overconfidence bias than women. In this sample, the magnitude of the overconfidence bias for both men and women is somewhat lower than what was reported by Pallier (2003). Thus, Cohen's *d*'s for the bias scores presented in Table 12 are 0.15 for Reading and 0.25 for Listening.

Table 13 presents ethnic group means (Whites, African Americans, and Hispanics) for the accuracy, confidence, and bias scores. The Hispanic group is in the middle on all three scores. It is evident that bias is greater for African American groups than it is for either White or Hispanic groups. On both the TOEFL iBT Reading and Listening sections, Whites show the smallest bias scores. In the next section, we elaborate on the finding that *F* tests for confidence are smaller than *F* tests for accuracy. Cohen's *d*'s for the Reading bias scores presented in Table 13 are 0.83 (Whites vs. African American), 0.46 (Whites vs. Hispanics), and 0.37 (African Americans vs. Hispanics). Listening bias scores produced similar effect sizes.

We broke down the African American sample further by college type—those who attend 2- or 4-year colleges. Table 14 shows the means for the composite accuracy, confidence, and bias scores for these subgroups. The differences on accuracy scores are not significant, whereas the differences on confidence are significant. African Americans in 2-year colleges show stronger bias than those attending 4-year colleges,  $t(110) = 4.07, p < .01$ . For Whites and Hispanics, the difference between 2- and 4-year colleges on bias was not statistically significant.

### Hard–Easy Effect and Overconfidence Bias

Tables 12, 13, and 14 show a consistent pattern: The between-group variability is lower for the confidence scores than it is for the accuracy scores. For instance, Table 13 shows that Whites on the TOEFL iBT Listening section demonstrate the highest accuracy score of 85.27, whereas African Americans on the TOEFL iBT Reading section show the lowest accuracy score of 61.75. The range for accuracy scores between groups is 23.52. On the other hand, the highest confidence score on the TOEFL iBT Listening section, 89.52, is reported for Whites, whereas the lowest confidence score, 83.02, is reported for African Americans. The range for confidence scores is only 6.50. Thus, the main difference in the bias scores between these ethnic groups is due to greater differences in the accuracy scores, not due to the confidence scores. Although groups of people who receive low accuracy scores express lower confidence in their answers, group differences in confidence scores do not change to the same order of magnitude as accuracy scores. Thus, bias is attributed to people's inability to judge the degree of the failure to solve test problems. Confidence is somewhat resistant to change even when people perform poorly on a test.

Within the framework of the present study, it is not just group differences that point to the variability in test difficulty as the factor most responsible for changes in bias scores. Arithmetic means for the whole sample displayed in Table 1 indicate that the Reading section is more difficult than the Listening section, but the average confidence differs little between the Listening and Reading sections. As a result, the Reading section shows an overconfidence bias that is more than twice as large as in the Listening section. What is known as a *hard–easy effect* in decision-making literature (see Suantak, Bolger, & Ferrell, 1996) may be one possible explanation for these differences. Put simply, the magnitude of overconfidence bias depends on task difficulty, and overconfidence bias tends to be more pronounced as the task becomes more difficult.

Instead of focusing on item difficulty, as it is usually done in discussions of the hard–easy effect, we can focus on participants and point out again that the results presented in Tables 12–14 show that groups with lower ability have larger overconfidence bias. This is in accordance with the assumption that higher ability

Table 12  
Means for Accuracy, Confidence, and Bias Scores on TOEFL iBT Reading and Listening Sections, Versions 1 and 2, by Gender

Group	Reading 1 and 2			Listening 1 and 2		
	Accuracy	Confidence	Bias	Accuracy	Confidence	Bias

\* *p* < .05. \*\* *p* < .01.

people have increased experience and are better at encoding stimuli (Dougherty, 2001). However, as we shall argue in the last section of this article, this correlation between overconfidence bias and ability may be due to individual differences in the understanding of subjective probability concepts (Kleitman, 2003; Stankov, Lee, & Paek, in press).

### Predictive Validity of Confidence Scores

In this section, we examine evidence for incremental predictive validity of confidence scores. In all the analyses we report, the scaled accuracy scores for the TOEFL iBT Reading and Listening section were entered as the first block of predictors, and the overall confidence scores were added in the second block. The question of interest was whether confidence can account for additional variance in the criterion that remains after accuracy scores are entered into the regression equation.

Table 15 presents  $R^2$  statistics as a summary index for regression analyses. A table note in the last column in Table 15 indicates scores with significant differences in the  $R^2$  between the two regression models; these are known as *incremental  $R^2$* . The criterion measures are three types of cognitive outcomes: (a) scores derived from TOEFL iBT (the total TOEFL iBT score as well as Speaking and Writing section scores), (b) numeracy and overclaiming  $d'$  test scores, and (c) self-reported SAT scores and HS-GPA. Table 15 shows that the confidence scores derived from TOEFL iBT Reading and Listening sections contribute significantly to the prediction of the total TOEFL iBT score, as well as TOEFL iBT Speaking and Writing section scores. The confidence scores provide statistically significant improvement in predicting Writing and Speaking scores that were not used in the assessment of confidence.<sup>5</sup> Of the two tests administered independently of TOEFL iBT, the numeracy test shows incremental validity for the confidence scores. The correlations between the overclaiming  $d'$  test and the confidence scores were low to begin with (see Table 7:  $r = .254$  for the Reading confidence score and  $r = .168$  for the Listening confidence score). Thus, the absence of any evidence for incremental validity for overclaiming  $d'$  is not entirely surprising. No evidence for incremental validity is found for the two self-reported scores: SAT and HS-GPA. For all three criterion scores that did not show incremental validity, we do not have any information about their reliability. We may note, however, that they are much broader than accuracy and confidence measures obtained from Listening and Reading tests.

In summary, the confidence scores from the two sections of TOEFL iBT do provide incremental validity over and above their yoked accuracy scores to the three independent sets of cognitive tests scores—speaking, listening, and numeracy. We can conclude that people's confidence scores can predict their cognitive abilities in some measures even after controlling for the cognitive abilities that are used as the basis for measuring confidence level. Reported incremental predictive validity is important from the theoretical point of view, as very few noncognitive measures have shown any incremental validity over cognitive measures (Schmidt & Hunter, 1998) when training or job success are used as criteria. This is particularly important because both accuracy and confidence measures arise from the same cognitive act and, in the case of total TOEFL iBT, the amount already predicted by the Reading and Listening accuracy scores themselves is very high indeed (87.5%). However, because the amount of variance accounted for by the confidence scores in this study is one percent or less, the practical importance of this finding is minimal.

On the other hand, it is reasonable to assume that confidence may have a much more prominent role in predicting criteria other than those closely linked to cognitive performance. For example, within the educational setting, confidence may be a good predictor of dropout rates, much better than many cognitive measures in existence today (see Kuncel & Hezlett, 2007). The evidence presented in this article also suggests that confidence may be a good predictor of repeated test taking in high-stakes assessments. In business settings where decision-making is crucial, the role of confidence is likely to be even more important.

### DISCUSSION

In this section we summarize the main findings of this study by focusing on three issues: (a) structural findings and their implications for the understanding of miscalibration, (b) group differences and problems associated with the use of bias scores, and (c) validity issues in the measurement of confidence and possible use of confidence ratings in assessment. In the last section we mention questions that may lead to future research.

<sup>5</sup> In the regression analyses of this article, we also entered an interaction score (i.e., a multiple of accuracy and confidence scores). This interaction score did not contribute significantly to any of the criterion measures (rows) in Table 15.

### Structural Findings and Their Implications

Our results are in agreement with previous work showing that confidence is an important psychological trait on the borderline between personality and cognitive abilities (Kleitman & Stankov, 2001, 2007; Pallier et al., 2002; Stankov, 1998, 1999, 2000; Stankov & Crawford, 1996, 1997). First, our results show that confidence measures have higher reliabilities than ability scores. Second, confidence should be considered as a separate trait, distinct from other traits such as ability and personality traits. The present study employed confidence scores based only on TOEFL iBT Reading and Listening scores, but previous work has shown that the confidence factor can be reliably extracted from a large number of cognitive tests. Our study also shows that confidence tends to be more closely related to cognitive abilities than it is to personality traits. This suggests that different types of confidence may exist—cognitive confidence, which is captured by the procedures of this article, versus social confidence, which can be measured as a part of personality. Third, although confidence appears to be conceptually related to processes captured by the questionnaire measures of metacognition, our evidence shows that confidence measures define a different factor. These findings provide support for construct validity of the confidence trait.

We believe that developmental evidence is needed to explain the existence of such a pervasive, i.e., general, cognitive confidence factor. Several studies are currently under way to examine the age at which children can be tested with the procedures described in this article. Our working hypothesis is that some factors within the school and family operate during the middle and high school periods to bring about this factor. The mechanisms are likely to be

Table 14

*Means for Accuracy, Confidence, and Bias Scores on Combined Reading 1 and 2 and Listening 1 and 2 Among African Americans by College Type*

College type	Accuracy	Confidence	Bias
2-year college	64.25	88.15	23.90
4-year college	66.39	81.15	14.76
<i>t</i> test <sup>a</sup>	1.53 ( <i>ns</i> )	2.97*	4.07*

<sup>a</sup> *df* = 110.

\* *p* < .05.

similar to those that lead to the appearance of the broad academic self-concept (see Guay, Marsh, and Boivin, 2003).

Identification of a new psychological trait is important from the individual differences point of view. Our findings, however, also have bearings on the explanation of miscalibration. Put simply, for a test made of items of the same difficulty, there are always individual differences in confidence that reflect a stable trait and therefore can be predicted using different measures of the same trait. For such a test confidence in addition to random error (Soll, 1996) can predict the amount of overconfidence bias.

### Group Differences and Problems With Measures of Overconfidence Bias

Three kinds of group differences have been identified: gender, ethnicity, and age. In this study, we found that men exhibit a stronger overconfidence bias than women. We also found differential overconfidence bias among ethnic groups, with African

Table 15

*R<sup>2</sup> Coefficients Showing Incremental Validity of Reading and Listening Confidence Scores in Predicting Various Accuracy Score Criteria Above and Beyond Reading and Listening Accuracy Scores*

Criteria	<i>R<sup>2</sup> from regression analysis</i>

<sup>a</sup> Reading and Listening accuracy scores. <sup>b</sup> Reading and Listening accuracy and confidence scores. <sup>c</sup> Statistically significant incremental validity change from the first model to the second model. <sup>d</sup> Subsample of *N* = 384.

\* *p* < .05. \*\* *p* < .01.

American students, particularly those attending 2-year colleges, showing the most pronounced overconfidence bias. Although one needs to be cautious in interpreting this finding because of the small sample, African Americans appear to be less aware of their level of performance on tests of verbal abilities than any other group in the present study, exhibiting the strongest bias. It seems plausible that overconfidence may lead to suboptimal effort and therefore contribute to the achievement gap. This may be an interesting avenue to pursue in future research on the topic. Finally, previous studies show age-related group differences: Older people are somewhat more confident than younger people (see Crawford & Stankov, 1996).

Our data also show that gender and ethnic group differences are smaller on confidence than they are on performance accuracy, implying that there is indeed a correlation between how difficult the task is for a given group and the size of the average overconfidence bias score. In other words, groups that have lower performance accuracy scores show higher overconfidence. This is in agreement with Dougherty's (2001) explanation of overconfidence bias in terms of increased experience and better encoding — i.e., the group with higher cognitive ability should show superior performance on tasks that depend on these processes.

However, the correlation between test difficulty (or participants' level of ability) and the amount of overconfidence bias needs to be examined carefully. The problem arises because of the issues associated with the measurement of subjective probability (confidence). For example, Stankov et al. (in press) point out that confidence ratings have a ceiling (100% confidence), and at least some of the subjects seem to interpret 50% confidence as chance performance, whereas others tend to use the full 20% to 100% range. Also, Kleitman (2003) argued that bias scores are indicative of systematic irrationality and correlate with several other biases identified by the heuristics and biases approach. Although these problems do not seem to seriously affect the measurement of confidence ratings per se, they do raise questions when we try to compare objective and subjective probability estimates. In addition, because bias scores are difference scores, they tend to have lower reliability than performance accuracy and confidence scores. It is for these reasons that the focus of this article is on confidence and not on measures of overconfidence bias.

### Validity of Confidence Scores

There is evidence for predictive validity of confidence scores. Thus, our results indicate that confidence ratings predict the amount of change in performance accuracy scores over two sessions of testing. This suggests that they may be indicative of repeated taking of high-stakes tests. Recent evidence also suggests that confidence scores are valuable in predicting some maladaptive personality styles, such as the feeling of being an impostor, also known as the "impostor phenomenon," which is characterized by a sense of inferiority, self-criticism, and a pervasive fear of the inability to replicate one's own success, despite previous evidence to the contrary. Want and Kleitman (2006) showed that people with a strong impostor disposition have lower confidence but not lower accuracy scores than those without such dispositions.

Our results also show an incremental validity of confidence scores for predicting cognitive performance on tests of writing, speaking, and numeracy. In particular, the incremental validity for

the numeracy test in this study underscores that confidence can be seen as a broad, task-independent trait. The absence of incremental validity evidence for self-reported SAT scores and HS-GPA may be due to the accuracy on self-reported test scores. Reliability of these self-reported scores is unknown. Possible low reliability of these self-reports may account for the low correlation between the confidence scores and both SAT scores and HS-GPA, and therefore be related to low incremental validity. From the practical point of view, the value of the obtained incremental validity is minimal.

The evidence for an incremental increase in the validity of confidence ratings suggests possible use of confidence if one wants to incorporate a noncognitive measure in service of selection, guidance, and intervention. It is the aspect of measurement employed in this study that makes confidence unique in comparison to other noncognitive measures. Of particular importance is the yoked nature of the confidence expressed in the answers to a specific test problem. This makes it difficult to fake an answer or to coach an examinee to answer in a particular way, which can occur in most other noncognitive measures. The presence of excessive bias scores can serve as a warning to the examiner that something may be amiss. The suggestion is that confidence ratings and bias scores may be useful as predictors of criteria other than cognitive performance. For example, they may be useful predictors of dropout rates or times to completion in graduate schools.

Finally, it is necessary to mention limitations on the findings reported in this article. These include possible effects of length of testing and fatigue on performance, the somewhat narrow range of ability levels of participants, and disproportionate cell sizes in ethnic group comparisons.

### Concluding Remarks

There are still quite a few unanswered questions about confidence. Some issues are relevant to the causal chain mentioned in relationship to achievement gap. For example, can general feedback on test performance reduce excessive confidence? Given that confidence has an incremental validity for predicting scores on the TOEFL iBT Speaking and Writing sections, does confidence have particular value in language learning? What is the relationship between confidence and personality measures other than the Big Five? For instance, how is ease in social interaction such as readiness to engage in public speaking related to cognitive confidence?

For over a century, the study of individual differences has focused on uncovering the dimensions that can be used to describe and perhaps understand the psychological make-up of the human species. Thus far, personality and ability domains have been mapped out reasonably well (see Carroll, 1993; Saucier & Goldberg, 2002). Every candidate for a new dimension in individual differences needs to be compared to what is known so far. At issue is a robust proof of its convergent and discriminant validity. Together with the findings from previous studies, the findings reported in this article indicate that confidence is indeed a psychological trait that is related to, but distinct from both personality and ability traits. Within the structure of all individual differences dimensions, confidence should be located between these two domains.

Université Laval

The purpose of this study was to determine the role of passion in teachers' burnout symptoms, work satisfaction, and perceptions of positive student classroom behaviors. The dualistic model of passion (Vallerand et al., 2003) proposes 2 types of passion: harmonious and obsessive. In previous studies, harmonious passion has been shown to lead to adaptive outcomes (e.g., well-being and satisfaction), whereas obsessive passion has been shown to lead to less adaptive outcomes (e.g., shame and negative affect). In this study, 494 teachers completed measures of passion for teaching and various outcomes associated with the teaching profession twice over a 3-month period. Results of a cross-lag model based on structural equation modeling revealed that increases in harmonious passion for teaching predicted increases in work satisfaction and decreases in burnout symptoms over time, while changes in obsessive passion were unrelated to such outcomes. In addition, increases in both harmonious and obsessive passion predicted increases in teacher-perceived adaptive student behaviors over time. Overall, the results of the present study suggest that passion for teaching is an important concept to consider in education.

**Keywords:** passion, teaching, student outcomes, burnout, work satisfaction

Passion is not a luxury, a frill, or a quality possessed by just a few teachers. It is essential to all good teaching. (Day, 2004, p. 11)

Teaching is a complex and demanding career that requires intense dedication. Daily difficulties teachers face include stress (Wilhelm, Dewhurst-Savellis, & Parker, 2000), inadequate support from the school administration, student discipline problems, and low salaries (Ingersoll, 2001). Every year, such harsh conditions make a number of teachers choose to leave the profession, which implies that those who stay committed to their position must feel a deep and genuine love for their job (Elliott & Crosswell, 2001). This is congruent with Day's (2004) claim that passion is essential in the teaching realm. Although the idea that passionate teachers have a positive impact on their students is widely accepted (Day, 2004; Fried, 1995; Patrick, Hisley, Kempler, & College, 2000), positions vary considerably as to the quality of personal outcomes

teachers derive from their passion. On one hand, some authors claim that passion in the workplace is the antidote to burnout because it characterizes people who are continually energized and reinvigorated by their work (Dlugos & Friedlander, 2001; Grosch & Olsen, 1994; Selder & Paustian, 1989). On the other hand, others consider that passion is one of the causes of burnout because it leads people to engage with too much intensity in a sphere of their life and neglect other life domains (Coulehan, 2002; Freudenberg, 1985; Marcil, 1991). Also, although the high level of commitment required by the teaching profession is a source of satisfaction for many teachers, others find the demands too great a burden (Day, 2004; Elliott & Crosswell, 2001) and report that teaching is "too absorbing" and "takes up too much of [their lives]" (Nias, 1989, p. 39).

How can passion lead a number of teachers to derive psychological well-being and satisfaction from their professional lives while driving others to be consumed by their teaching to the point where they end up suffering and experiencing negative emotions and burnout? Although much has been written about passion for teaching, very little empirical research and no formal theory or model seem to exist. The purpose of the present study was to attempt to address the above question by using a new conceptualization of passion (Vallerand et al., 2003).

## A Dualistic Model of Passion

Vallerand et al. (2003) defined passion as a strong inclination or desire toward an activity (e.g., one's job) that one likes (or even loves) and finds important and in which one invests time and energy. We further posit that the representation of an activity that

one likes and in which one engages on a regular basis will be incorporated in that person's identity to the extent that the activity is highly valued (Aron, Aron, & Smollan, 1992; Csikszentmihalyi, Rathunde, & Whalen, 1993), thereby leading to a passion for this activity. Such a passionate activity comes to be so self-defining that it represents a central feature of one's identity. For instance, those who have a passion for teaching do not merely say that they teach; they *are* teachers.

The passion model distinguishes two types of passion: harmonious and obsessive passion. There are two different processes by which an activity can be internalized in one's identity, each of them resulting in a specific type of passion. Harmonious passion emanates from an autonomous internalization (Deci & Ryan, 2000; Vallerand, 1997) of the activity into one's identity. Such an internalization occurs when an individual freely accepts an activity as important to him or her. No contingencies are attached to the passionate activity such that activity engagement is personally endorsed. The autonomous internalization comes from an intrinsic tendency of the self (Deci & Ryan, 1985, 2000, 2002; Ryan & Deci, 2003) and produces a motivational force to engage in the activity willingly (Vallerand, 1997; Vallerand, Fortier, & Guay, 1997). Individuals do not feel an uncontrollable urge to engage in the passionate activity, but rather freely choose to do so. Thus, when it comes to harmonious passion, behavioral engagement can be seen as flexible: People are able to decide when and when not to engage in the activity. For example, a teacher with a harmonious passion for teaching who is offered an opportunity to give a tutorial class at lunchtime might decide to decline the offer because such a task would reduce time that should be devoted to relaxing, reenergizing, and socializing with colleagues. The harmoniously passionate activity (e.g., teaching) can be seen as occupying a significant but not overpowering space in the person's identity and is in harmony with other aspects of the person's life (Vallerand et al., 2003). This should lead people with a harmonious passion to be able to fully concentrate on the task at hand and experience positive outcomes both during activity engagement (e.g., positive affect and flow) and after activity engagement (e.g., satisfaction or no guilt). Moreover, when prevented from taking part in their passionate activity, they should be able to focus their attention and energy on other tasks, without constantly ruminating about the passionate activity.

Conversely, obsessive passion results from a controlled internalization (Deci & Ryan, 2000) of the activity into one's identity. Such an internalization originates from intrapersonal or interpersonal pressure either because certain contingencies are attached to the activity, such as feelings of social acceptance or self-esteem, or because the sense of excitement derived from activity engagement becomes uncontrollable. For instance, although a teacher really enjoys his profession, he might experience an internal desire to teach because it is the only activity that might allow him to maintain a sense of self-worth. In such a case, teaching is no longer a truly volitional choice, but rather an activity this individual feels he *has* to do (e.g., to feel like a worthy person). People with an obsessive passion are controlled by their activity; it is as if they cannot help but to engage in it. Because the activity becomes out of one's control, it can take up disproportionate space in a person's life. This can lead one to neglect other life domains (e.g., family, friends, and leisure), thereby resulting in conflict in one's life. For

instance, a teacher with an obsessive passion for teaching might agree to partake in a committee organizing school activities—in addition to her regular class assignment—although such additional tasks would overload her and conflict with family activities. While attending the committee's meetings, she might be upset with herself for working instead of being at home with her husband and children. She might therefore have difficulties focusing on her task and may not experience positive affect while doing it. She might even feel guilty afterward. Thus, because of its controlled nature, it is proposed that obsessive passion can eventually lead to less adaptive outcomes. Although some benefits (e.g., improved teaching skills) might follow from this type of passionate involvement, so do harsh costs (e.g., personal and family problems and burnout).

Research has provided empirical support for several aspects of the passion conceptualization. First, the existence of two constructs, corresponding to harmonious and obsessive passion, has been supported by results from exploratory and confirmatory factor analyses with the Passion Scale (Rousseau, Vallerand, Ratelle, Mageau, & Provencher, 2002; Vallerand et al., 2003, Study 1; Vallerand et al., 2006, Study 1). Second, partial correlations (controlling for the correlation between the two types of passion) revealed that both harmonious and obsessive passion were positively associated with measures of activity valuation and measures of the activity being perceived as a passion, thereby providing support for the definition of passion. Empirical evidence has also shown that the two types of passion are associated with different affective experiences (Vallerand et al., 2003, Study 1). Thus, harmonious passion is positively associated with flow and positive emotions experienced during activity engagement, whereas obsessive passion is positively associated with negative emotions (e.g., shame) after engagement with the activity and when prevented from engaging in the activity altogether. Obsessive (but not harmonious) passion is also related to conflict with other aspects of one's life (Séguin-Lévesque, Laliberté, Pelletier, Blanchard, & Vallerand, 2003; Vallerand et al., 2003, Study 1), to rumination and negative affect when the person is prevented from engaging in the passionate activity (Ratelle, Vallerand, Mageau, Rousseau, & Provencher, 2004; Vallerand et al., 2003, Study 1), and to rigid persistence in ill-advised activities (Vallerand et al., 2003, Studies 3 and 4), eventually leading to chronic injuries in dancers (Rip, Fortin, & Vallerand, 2006) and to pathological gambling (Philippe & Vallerand, 2007; Ratelle et al., 2004).

It should be noted that support for these findings has been obtained in a variety of activities including work (Vallerand & Houliort, 2003), gambling (Mageau, Vallerand, Rousseau, Ratelle, & Provencher, 2005; Ratelle et al., 2004; Rousseau et al., 2002), Internet use (Séguin-Lévesque et al., 2003), sports (Vallerand et al., 2003, Study 2; Vallerand & Miquelon, 2007; Vallerand et al., 2006), and several types of recreational activities such as reading and playing music (Vallerand et al., 2003, Study 1).

### On Passion for Teaching: The Present Research

Passion appears to be an important concept to consider in education because the teaching profession requires teachers to invest time, energy, and their hearts in their teaching (Day, 2004). Passion is not only what attracts and keeps teachers in the profession (Nias, 1996), it is also what makes them constantly search for

more effective ways to reach their students and master their craft (Zehm & Kottler, 1993). Thus "passion is not an option. It is essential to high-quality teaching" (Day, 2004, p.3). Although several authors have emphasized the importance of passion in the teaching profession (Day, 2004; Elliott & Crosswell, 2001; Fried, 1995; Nias, 1996), the construct has not yet been the subject of extensive empirical research. The scientific study of passion in the teaching realm is especially relevant because paradoxical conceptions of passion have been proposed in the education literature. Thus, it appears that "passion can lead to enhanced vision [. . .] but it can also restrict wider vision and lead to the narrow pursuit of a passionately held conviction at the expense of other things" (Day, 2004, p. 11). The main purpose of the present research, therefore, was to use the recent theoretical framework of passion proposed by Vallerand et al. (2003) to provide a better understanding of the role of passion for teaching in various teacher and student outcomes.

School boards and administrators are increasingly concerned with teachers' professional satisfaction and burnout, two personal outcomes that play a crucial role with regards to teachers' intentions to stay committed (or not) to their jobs (Fore, Martin, & Bender, 2002; Shann, 1998). Although no empirical study has looked directly at the relationship between passion for teaching and professional outcomes, research on passion in other domains has clearly suggested that harmonious and obsessive passion should be differently associated with satisfaction and burnout in the teaching realm. Indeed, in previous studies, harmonious passion has been shown to lead to a number of adaptive outcomes, including enhanced subjective well-being and vitality (Rousseau & Vallerand, 2003, 2006; Vallerand et al., 2006, 2007, 2008), reduced depression and anxiety, positive affective experiences at work (Vallerand & Houliort, 2003), and positive emotions during and after engagement in the passionate activity (Vallerand et al., 2003, Study 1). Conversely, obsessive passion has been associated with maladaptive outcomes such as reduced work satisfaction (Vallerand & Houliort, 2003) and negative emotions both during and after engagement in the passionate activity (Vallerand et al., 2003, Study 1). Thus, one purpose of the present study was to replicate and extend past findings on the more adaptive outcomes derived from harmonious (vs. obsessive) passion with respect to work satisfaction and burnout.

Much has been written about the potential of passion for teaching to produce student benefits (e.g., Day, 2004; Fried, 1995). However, to the best of our knowledge, no empirical work has tested this relationship. Obsessive and harmonious passion should lead to positive student outcomes because enthusiasm, which is a key overt characteristic of passion (Selder & Paustian, 1989), has been shown to promote students' vitality (Patrick et al., 2000). Another purpose of this study was therefore to remedy the lack of research concerning the role that teachers' passion may play in students' adaptive classroom behaviors. An additional purpose was to use a cross-lag panel model to test for the directionality of effects between passion and outcomes. Specifically, such a design allowed us to determine whether changes in harmonious and obsessive passion predicted changes in outcomes (i.e., work satisfaction, burnout, and teacher-perceived student behaviors) over time or, conversely, whether changes in outcomes predicted changes in passion. A final and exploratory purpose of the present study was to assess the prevalence of passion in the teaching realm.

Overall, we made a number of predictions. First, we expected increases in harmonious passion to predict increases in work satisfaction over time and increases in obsessive passion either to predict losses of work satisfaction or to be unrelated to it. Second, we hypothesized that increases in harmonious passion would predict losses in burnout symptoms over time, whereas we expected increases in obsessive passion either to predict increases in burnout symptoms or to be unrelated to them. Third, we expected increases in both harmonious and obsessive passion to predict enhanced perceptions of positive student behaviors over time. Fourth, although we hypothesized that changes in harmonious and obsessive passion at Time 1 would predict changes in specific outcomes (as detailed above), we did not expect the reverse. That is, we did not expect changes in work satisfaction, burnout symptoms, and teacher-perceived student classroom behaviors to predict changes in both types of passions. Finally, we hypothesized that a majority of teachers would be passionate.

## Method

### Participants

Participants were 494 teachers (373 women, 119 men, and 2 who did not identify their gender) from French-Canadian schools in two school boards from the Quebec City area. Our sample consisted of 306 elementary teachers, 120 high school teachers, 20 teachers in adult education, 46 teachers in vocational and technical education, and 2 who did not specify their school level. Age ranged from 23 to 64 years ( $M = 43.07$  years,  $SD = 10.16$ ). The mean number of years of teaching experience was 15.82 years ( $SD = 10.33$ ). A total of 653 participants took part at Time 1; of these, 494 also took part at Time 2, yielding a response rate of 75.7%.<sup>1</sup>

### Procedure

This study was conducted over a 3 month-period and consisted of two data collections (i.e., March and June). At each phase of the study, teachers were asked to fill out a questionnaire and return it in a prestamped envelope. Follow-up telephone calls were made to increase the return rate.

### Instruments

**Passion.** The Passion Scale (Vallerand et al., 2003) contains two sections. The first assesses the extent to which people have a passion for an activity (i.e., teaching in the present study). The level of passion is measured with the mean of four criterion items that reflect the definition of passion. Specifically, participants are asked to report the extent to which they value the activity, devote time to it, love it, and view it as a passion (see appendix). These four items were highly intercorrelated in the present study: the

<sup>1</sup> Respondents who took part in both phases of the study were significantly older and had more years of experience as a teacher (as assessed at Time 1) than respondents who only took part in Time 1. However, controlling for those variables in the model did not change the pattern of results.

Table 1  
Means, Standard Deviations, and Correlations Involving the Latent Variables of the Model

Variable	M	SD	1	2	3	4	5	6	7	8	9	10
1. Harmonious passion (at T1)	4.92	1.02	—									
2. Obsessive passion (at T1)	2.65	1.04	-.14*	—								
3. Work satisfaction (at T1)	4.44	1.16	.73**	-.07	—							
4. Burnout (at T1)	1.97	1.00	-.63**	.38**	-.74**	—						
5. Positive student behaviors (at T1)	2.85	0.56	.32**	.02	.40**	-.36**	—					
6. Harmonious passion (at T2)	4.95	1.02	.80**	-.11*	.58**	-.50**	.26**	—				
7. Obsessive passion (at T2)	2.59	1.06	-.13**	.88**	-.06	.34**	.01	-.10*	—			
8. Work satisfaction (at T2)	4.50	1.20	.71**	-.08	.83**	-.63**	.34**	.73**	-.09*	—		
9. Burnout (at T2)	2.00	1.04	-.62**	.31**	-.66**	.85**	-.32**	-.60**	.32**	-.70**	—	
10. Positive student behaviors (at T2)	2.90	0.59	.36**	.10*	.38**	-.31**	.78**	.31**	.09*	.38**	-.36**	—

Note.  $N = 494$ ; all scales were assessed on a 7-point scale except for teacher-perceived student behaviors, which were assessed on a 4-point scale. T1 = Time 1; T2 = Time 2.

\*  $p < .05$ . \*\*  $p < .01$ .

Cronbach's alphas were .79 and .78 at Times 1 and 2, respectively. The second section of the Passion Scale assesses harmonious and obsessive passions with two six-item subscales. In the present study, harmonious and obsessive passions were found to be unrelated ( $r_s = .01$  and  $.00$ , at Times 1 and 2, respectively).<sup>2</sup> A sample item for harmonious passion is "My job as a teacher is in harmony with the other activities in my life"; a sample item for obsessive passion is "I have almost an obsessive feeling for my job as a teacher." The Cronbach's alpha values for these two subscales were .87 and .76, respectively, at Time 1 and .87 and .80, respectively, at Time 2. Responses to all items were scored on a 7-point Likert scale ranging from 1 (*do not agree at all*) to 7 (*very strongly agree*). Much support exists for the validity and the reliability of the Passion Scale (see Rousseau et al., 2002; Vallerand et al., 2003, 2006). In this study, a confirmatory factor analysis of the Passion Scale yielded an acceptable fit to the data,  $\chi^2(23, N = 494) = 138.12, p < .001$ , comparative fit index = .96, normed fit index = .95, standardized root-mean-square residual = .08, root-mean-square error of approximation = .10, confidence interval = [.09–.12].

**Work satisfaction.** We assessed work satisfaction with the French-Canadian version (Blais, Vallerand, Pelletier, & Brière, 1989) of the Satisfaction With Life Scale (Diener, Emmons, Larsen, & Griffin, 1985), adapted to the worklife for the purpose of this study. The instrument consists of five items that are measured on a 7-point Likert scale, ranging from 1 (*strongly disagree*) to 7 (*strongly agree*). A sample item is "In most ways my job is close to my ideal." The Cronbach's alphas in this study were .88 and .90 at Times 1 and 2, respectively.

**Burnout.** Burnout was assessed using the French-Canadian version (Dion & Tessier, 1994) of the Maslach Burnout Inventory (Maslach & Jackson, 1986). The psychometric properties of the French-Canadian version of the Maslach Burnout Inventory are similar to those of the original version (see Dion & Tessier, 1994). The instrument measures three dimensions of burnout: emotional exhaustion, depersonalization, and personal accomplishment. However, in line with past research (Coders & Dougherty, 1993; Shirom, 2003), we used only the first two dimensions—considered the "core of burnout"—in the present study. Emotional exhaustion (nine items) is characterized by a lack of energy and a feeling that

one's emotional resources are used up (e.g., "I feel emotionally drained from my work"). Depersonalization (five items) refers to a negative, callous, and detached attitude toward the people with whom one works (e.g., "I feel I treat some students as if they were impersonal objects"). Responses were scored on a 7-point Likert scale varying from 1 (*never*) to 7 (*everyday*). The Cronbach's alpha values were .70 and .77 for depersonalization and .92 and .93 for emotional exhaustion, at Times 1 and 2, respectively.

**Teacher-perceived student behaviors.** We used three items from the French-Canadian version (Fernet & Senécal, 2004) of the Pupil Behavior Patterns Scale (Friedman, 1995) to assess teachers' perceptions of student behavior patterns. Responses were scored on a 4-point Likert scale varying from 1 (*never*) to 4 (*very often*). A sample item was "Students in my class are cooperative and enthusiastic." High scores are indicative of adaptive student classroom behaviors. The Cronbach's alphas in this study were .73 and .75 at Times 1 and 2, respectively.

## Results

Means, standard deviations, and correlations of the model variables are presented in Table 1. We performed all structural equation modeling analyses on a raw data file using maximum likelihood estimation procedure (EQS version 6.1; Bentler, 1993). The model tested in the present study was composed of 10 latent variables: 5 exogenous variables (i.e., harmonious passion, obsessive passion, work satisfaction, burnout, and student behaviors at Time 1) and 5 endogenous variables (i.e., harmonious passion, obsessive passion, work satisfaction, burnout, and student behaviors at Time 2). As shown in Figure 1, each latent variable had between two and five indicators. The three items of the Pupil Behavior Patterns Scale were used as the indicators of the student behaviors factor, and the five items of the Work Satisfaction Scale were used as the indicators of the work satisfaction latent variable.

<sup>2</sup> Correlations between harmonious and obsessive passions have been found to vary across studies. This would suggest that whether the two types of passion are orthogonal or not may be a function of the type of activity at hand.

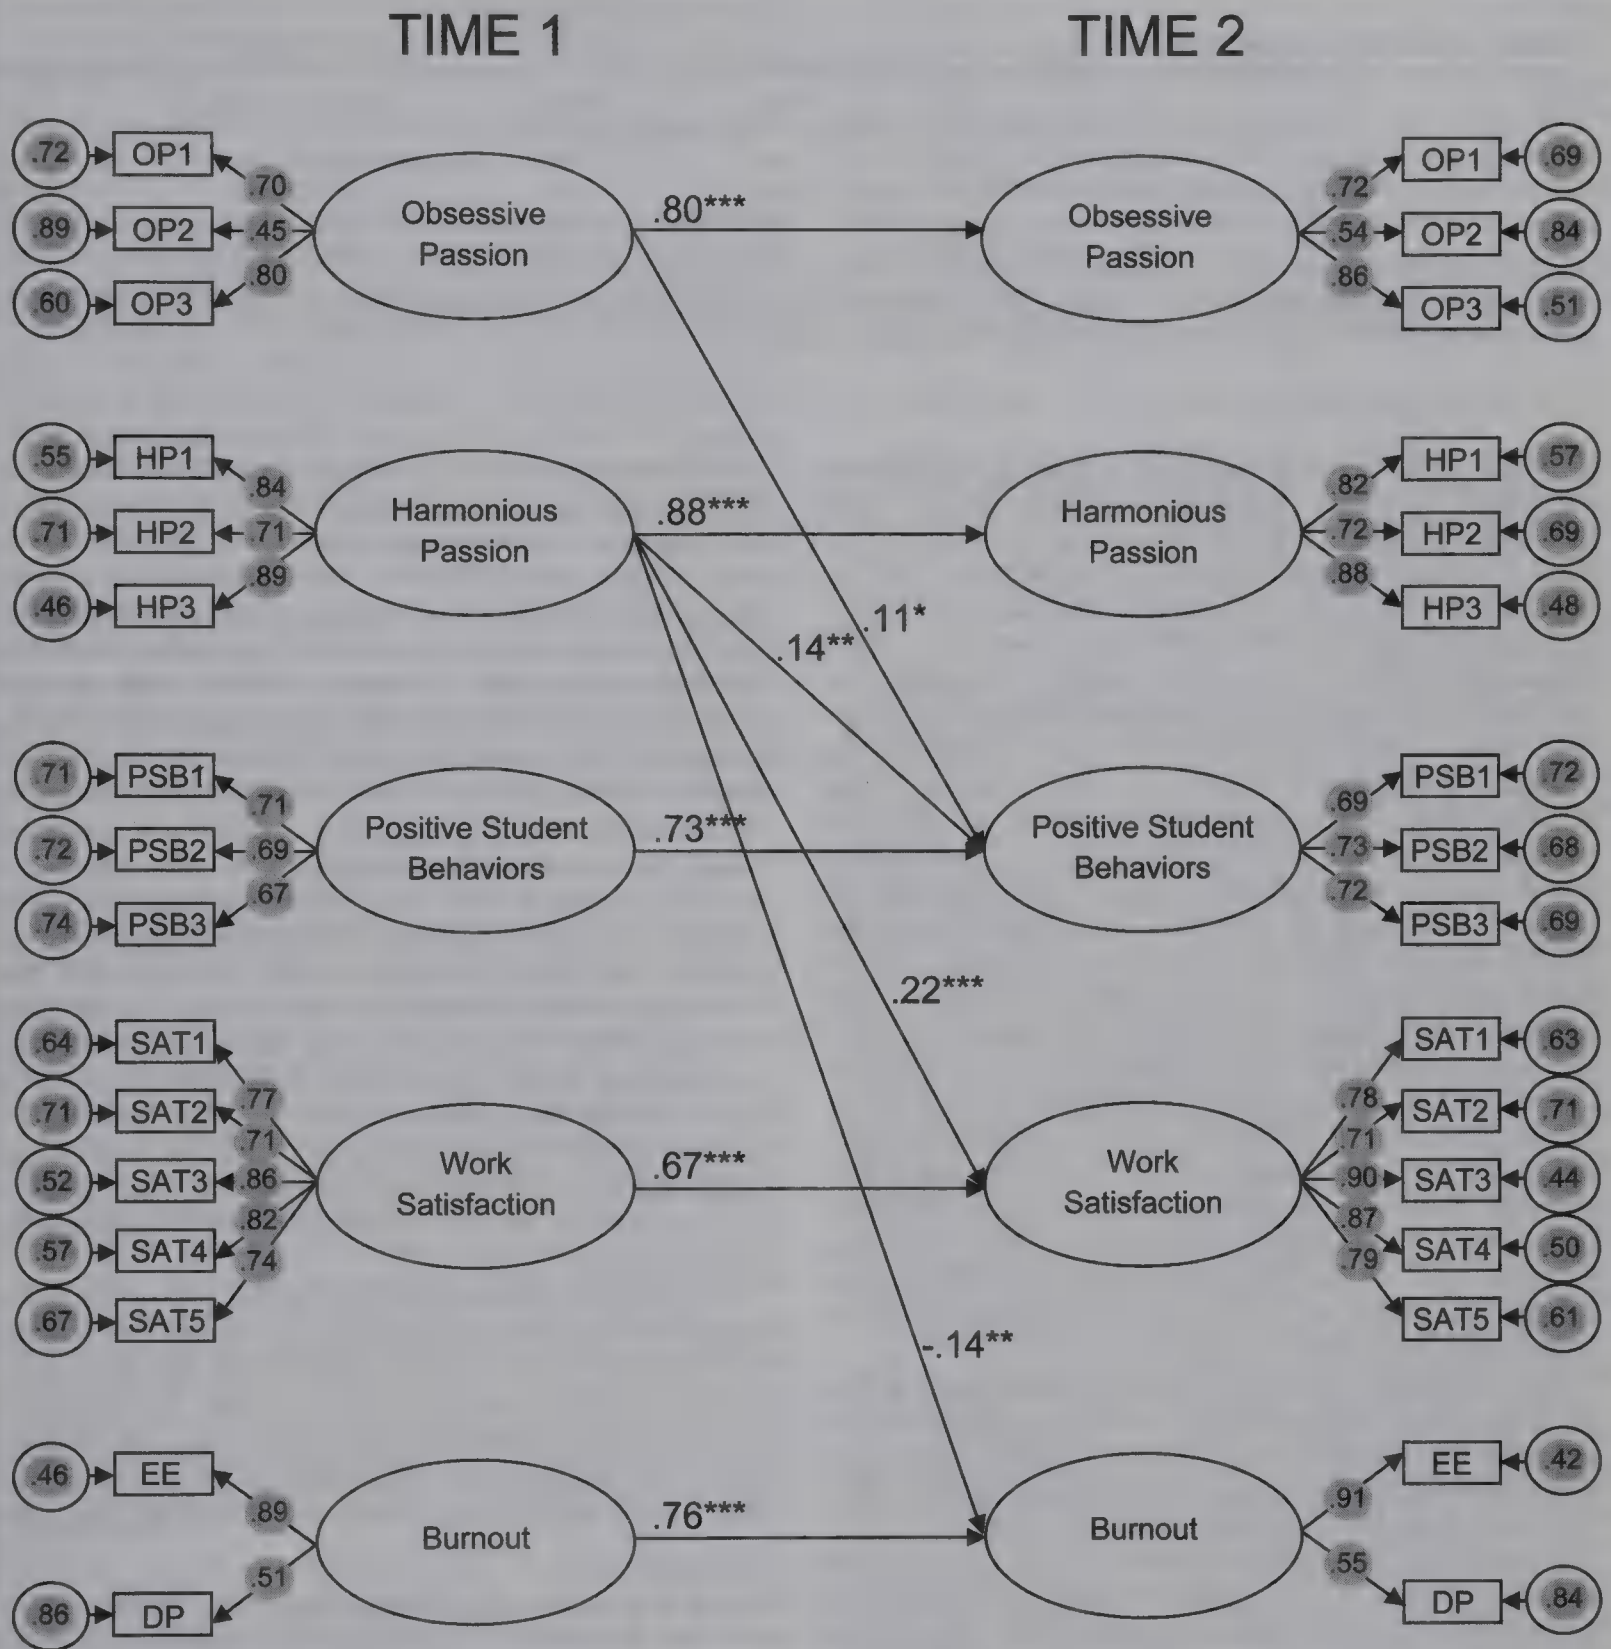

Figure 1. Results of the structural equation modeling analyses.  $N = 494$ . \* $p < .05$ . \*\* $p < .01$ . \*\*\* $p < .001$ .

Because the variables contained too many items, parcels were used as indicators of the two types of passion as well as the burnout latent variable. For harmonious and obsessive passion, we computed parcels by aggregating Items 1 and 2 from their respective subscale into Parcel 1, Items 3 and 4 into Parcel 2, and Items 5 and 6 into Parcel 3. Parcels were also used for the burnout variable, in which we aggregated items from the Emotional Exhaustion subscale into Parcel 1 and items from the Depersonalization subscale

into Parcel 2. Following suggestions by Marsh and Hau (1996), we allowed each of the 16 indicators at Time 1 to covary with its equivalent at Time 2 to prevent inflated estimates of stability. We estimated the covariances between the five latent constructs at Time 1 and the covariances between the disturbance terms at Time 2. For clarity concerns, we omitted covariances in Figure 1.

To test the hypotheses of the present study, we tested a first model. A total of 11 paths were specified: one between each

Table 2  
*Goodness-of-Fit Indices of the Four Models*

Model	$\chi^2$	df	CFI	NFI	SRMR	RMSEA and CI	AIC
1	949.67	417	.95	.91	.08	.05 (.05-.06)	115.67
2	952.43	419	.95	.91	.08	.05 (.05-.06)	114.43
3	972.45	417	.95	.91	.08	.05 (.05-.06)	138.45
4	941.79	411	.95	.91	.08	.05 (.05-.06)	119.79

*Note.* CFI = comparative fit index; NFI = normed fit index; SRMR = standardized root-mean-square residual; RMSEA = root-mean-square error of approximation; CI = confidence interval; AIC = Akaike's information criterion.

variable at Time 1 and its equivalent at Time 2, one between harmonious passion at Time 1 and each outcome (i.e., work satisfaction, burnout, and teacher-perceived student behaviors) at Time 2, and one between obsessive passion at Time 1 and the outcomes at Time 2. The results showed that the model had an acceptable fit to the data,  $\chi^2(417, N = 494) = 949.67, p < .001$ , comparative fit index = .95, normed fit index = .91, standardized root-mean-square residual = .08, root-mean-square error of approximation = .05, confidence interval = [.05-.06]. Because the chi-square is sensitive to sample size, some researchers have suggested using the normed chi-square, which is the chi-square value divided by the degrees of freedom (Kline, 2005). Bollen (1989) suggested that a normed chi-square value of less than 3.0 indicates a reasonable fit to the data. In the present study, the normed chi-square value was 2.28 (949.67/417). Results revealed that all paths but two (i.e., those from obsessive passion to work satisfaction and burnout) were significant. We conducted the analyses again, omitting the two nonsignificant paths. The model fit indices remained virtually unchanged, as shown in Table 2 (see Model 2). To compare the two models, we used Akaike's information criterion (AIC) statistic. Within a set of competing nonhierarchical models, the one with the lowest AIC value is preferred (Kline, 2005). The original model yielded an AIC of 115.67. The model in which two paths were omitted (i.e., Model 2) was kept because it yielded an AIC of 114.43, which indicates that it was slightly more parsimonious than Model 1.

The standardized solutions for Model 2 are presented in Figure 1. Each latent variable at Time 1 was strongly and positively associated with its equivalent at Time 2 ( $\beta$ s ranging from 0.67 to 0.88), suggesting that the constructs are relatively stable over time. Although a large part of the variance of each outcome at Time 2 was explained by the equivalent outcome at Time 1, a significant part of the variance of those outcomes was nevertheless explained by either one (for work satisfaction and burnout) or both (for student behaviors) types of passion at Time 1. More specifically, increases in harmonious passion predicted increases in work satisfaction ( $\beta = 0.22$ ) and increases in teacher-perceived adaptive student behaviors ( $\beta = 0.14$ ), as well as decreases in burnout ( $\beta = -0.14$ ) that took place over the 3-month period. We also found that increases in obsessive passion predicted an increased perception of adaptive student behaviors ( $\beta = 0.11$ ) from Time 1 to Time 2.<sup>3</sup>

We tested two alternative models. The first alternative model (i.e., Model 3) considered in this study was one in which the paths from outcomes (i.e., work satisfaction, burnout, and student behaviors) at Time 1 to harmonious and obsessive passions at Time

2 were estimated in addition to the paths from all five variables at Time 1 to their equivalents at Time 2. We tested such a model to help determine the directionality of effects (i.e., whether harmonious and obsessive passions are the antecedents and not the consequences of work satisfaction, burnout, and perceived student behaviors). As can be seen in Table 2, this model resulted in increased chi-square and AIC values. Moreover, results revealed the absence of significant paths from the outcomes at Time 1 to the two types of passion at Time 2. Model 3 was therefore rejected. Finally, we tested another alternative model involving reciprocal effects (i.e., Model 4). In such a model, the paths from passions at Time 1 to outcomes at Time 2 and the paths from outcomes at Time 1 to passions at Time 2 were estimated simultaneously. The model fit indices are shown in Table 2. Model 4 provided no additional information in comparison to the previous models; that is, the paths from harmonious passion at Time 1 to the three outcomes at Time 2 were significant, as was the path from obsessive passion at Time 1 to teacher-perceived student behaviors at Time 2, whereas no significant relations were found between the outcomes at Time 1 and the passions at Time 2. For those reasons and because the model AIC value was higher than that of Model 2 (119.79 > 114.43), the latter was preferred, thereby supporting the proposed model.

As a final and exploratory purpose, we had proposed to assess the prevalence of passion for teaching in our sample. We used the four criteria of passion (i.e., activity valuation, time investment, love for the activity, and activity being a passion; Vallerand et al., 2003) to differentiate between the nonpassionate and the passionate teachers. Teachers with a mean score on the sum of the four criteria at the midpoint (4) or above on the response scale were

<sup>3</sup> The model was also tested with estimated missing values at Time 2 ( $N = 653$ ) using the full-information maximum likelihood method. The same results were obtained. Furthermore, we tested a Time-1-only model and a Time-2-only model. In the Time-1-only model, harmonious passion was positively associated with satisfaction ( $\beta = 0.78$ ) and student behavior ( $\beta = 0.38$ ) and negatively associated with burnout ( $\beta = -0.63$ ), whereas obsessive passion was positively associated with burnout ( $\beta = 0.28$ ). In the Time-2-only model, harmonious passion was positively associated with satisfaction ( $\beta = 0.81$ ) and student behavior ( $\beta = 0.38$ ) and negatively associated with burnout ( $\beta = -0.65$ ), and obsessive passion was positively associated with burnout ( $\beta = 0.27$ ) and student behavior ( $\beta = 0.14$ ). Both models yielded acceptable fits to the data. Thus, both Time-1-only and Time-2-only models yielded the same basic results as the model involving both time points. We feel that these results provide additional support for our model.

classified as passionate. Results showed that 93.1% of the teachers in the present study were at least moderately passionate about their teaching.<sup>4</sup>

## Discussion

The general purpose of the present research was to proceed to the empirical study of passion in the teaching realm to achieve a better understanding of the intrapersonal and interpersonal outcomes associated with it. Specifically, we sought to shed light on the role of changes in harmonious and obsessive passions in the changes in work satisfaction, burnout, and teacher-perceived positive student behaviors that take place over time. We expected increases in harmonious passion to predict an augmentation of work satisfaction and a reduction of burnout symptoms over time. Conversely, we expected increases in obsessive passion either to predict a reduction of work satisfaction and an augmentation of burnout symptoms over time or to be unrelated to those outcomes. Moreover, we expected increases in both harmonious and obsessive passions to predict increases in teacher-perceived positive student behaviors over time. Finally, we hypothesized that most teachers would be passionate toward their job. Overall, the results of the present research provided support for all these hypotheses.

### *On Passion for Teaching and Intrapersonal Outcomes*

An important conclusion that may be drawn from the present findings has to do with the relationships between passion and intrapersonal outcomes. In line with our hypotheses, increases in harmonious passion were shown to predict increases in job satisfaction and decreases in burnout symptoms over time, and increases in obsessive passion were shown to be unrelated to such outcomes. These findings are particularly interesting because they shed some light on the following inconsistency: Passion seems to lead some teachers to fully enjoy themselves in their jobs, whereas others do not appear to derive such positive benefits (Day, 2004; Nias, 1989). Therefore, our results support the assumption that the quality of outcomes derived from one's teaching depends on the type of passion held by the teacher. It would thus appear that involvement in an activity central to one's life (such as teaching) contributes to one's personal well-being to the extent that harmonious passion underlies such involvement. Conversely, high activity involvement triggered by obsessive passion may not afford similar benefits.

Future research is needed to identify the psychological processes through which harmonious passion is linked to reduced burnout and enhanced job satisfaction. Past research on passion has shown that during task engagement, harmonious passion is associated with positive affect, whereas obsessive passion is unrelated to positive affect and can even predict negative affect (Mageau et al., 2005; Vallerand et al., 2003, Study 1). Thus, one plausible explanation for the effect of harmonious passion on the intrapersonal outcomes may have to do with the fact that engaging in an activity (such as teaching) out of harmonious passion leads to the cumulative experience of positive affect, which over time translates into increased satisfaction and subjective well-being. This would be consistent with research by Fredrickson and Joiner (2002) that has shown the existence of an upward spiral, whereby positive affect leads to higher levels of subjective well-being that

lead to subsequent experiences of positive affect, and so on. Such a spiral may be triggered by the impact of harmonious passion on positive affect. Similarly, a downward spiral involving negative affect and subjective well-being might also exist and may be induced by obsessive passion. In fact, research with elderly individuals by Rousseau and Vallerand (2003, 2008) has suggested that harmonious passion could lead to positive affect that, in turn, leads to increased subjective well-being. The role of affect as a mediator between passion for teaching and intrapersonal outcomes should be more fully examined in future research.

### *On Passion for Teaching and Interpersonal Outcomes*

The present research provides valuable information on the role of passion for teaching in teacher-perceived student outcomes. Thus, increases in both types of passion were shown to lead to increases in teacher-perceived adaptive student classroom behaviors over a 3-month period. Although this result is in line with many authors' claims that teachers who display a passion for their teaching have a positive impact on their students (Day, 2004; Fried, 1995), this study was the first to test this sequence within a theoretical framework. The finding that harmonious and obsessive passion have a similar and positive impact on others is interesting because the two types of passion are fueled by quite different processes. Thus, on one hand, obsessive passion originates largely from ego-invested structures within the person (Hodgins & Knee, 2002), which lead the individual to be defensive and to not open up to the world. On the other hand, harmonious passion emanates from the authentic integrating self (Deci & Ryan, 2000; Hodgins & Knee, 2002) and allows the individual to fully open up to various experiences. We suggest that students might perceive the vitality, intensity, and enthusiasm (Patrick et al., 2000) common to harmonious and obsessive passion because those are visible signs of passion. However, we posit that students are unaware of the processes underlying the two types of passion and, therefore, would not be expected to distinguish an obsessively passionate from a harmoniously passionate teacher. This would explain why increases in teacher-perceived positive student behaviors were positively predicted by increases in both harmonious and obsessive passions, although teachers themselves did not derive the same personal benefits from the two types of passion. Further examination of the interpersonal impact of passion is clearly needed. In fact, although the type of passion a teacher experiences does not seem to make a difference for students, it may not be the case for other individuals surrounding passionate teachers. Indeed, research by Séguin-Lévesque et al. (2003) revealed that obsessive passion toward the Internet was positively associated with conflict in the couple relationship but negatively related to dyadic adjustment. In contrast, harmonious passion toward the Internet was associated with less conflict and greater dyadic adjustment. Future research should investigate whether harmoniously and obsessively passionate teachers might have different impacts on significant others such as spouses and colleagues.

Another issue related to the interpersonal domain would be whether the two types of passion lead to different interpersonal

<sup>4</sup> Removing the nonpassionate teachers ( $N = 34$ ) from the analyses did not change the pattern of results. Therefore, these participants were not excluded.

effects as a function of the kind of activities at hand. Although there might be no visible signs allowing others to distinguish teachers' harmonious passion from their obsessive passion in the classroom, it could be otherwise in other settings. For example, in the physical activity realm, a teacher with an obsessive passion might be seen as more aggressive and competitive by people surrounding him or her than one with a harmonious passion. These different types of passion might lead to different effects on students. Such a hypothesis constitutes an interesting research avenue to explore.

### *Implications for the Dualistic Model of Passion*

Another implication from the present results pertains to the support they provide for the dualistic model of passion. Our findings first document the differential influences of harmonious and obsessive passion on the intrapersonal level. They showed that although obsessive passion is unrelated to well-being benefits, harmonious passion can make a significant difference in teachers' lives by boosting job satisfaction and decreasing the risks of burnout over time. These results are congruent with those from previous studies that demonstrated that harmonious passion is associated with more adaptive outcomes than is obsessive passion (Mageau et al., 2005; Ratelle et al., 2004; Rip et al., 2006; Rousseau & Vallerand, 2003, 2008; Vallerand et al., 2003, 2006). Although results showed that changes in obsessive passion did not predict changes in burnout symptoms, it is worth noting that there was an association between these two variables when the measurement times were considered separately ( $\beta = 0.28$  at Time 1 and  $\beta = 0.27$  at Time 2).

The present study also yielded important findings with respect to interpersonal influences of passion (Vallerand et al., 2003). Results revealed that although divergent at the intrapersonal level, outcomes associated with harmonious and obsessive passions for teaching converge at the interpersonal level. Specifically, results showed that both types of passion foster adaptive student behaviors in the classroom, as perceived by the teacher. They also suggest that the mere fact of being passionate for one's teaching would be enough to instill adaptive student classroom behavior. Future research is needed to identify the nature of the psychological processes that mediate the positive effects of passion on such student adaptive behavior. For instance, does teacher's enthusiasm (Patrick et al., 2000) induced by passion represent a crucial mediator of such effects? This hypothesis should be tested in future research.

Results also provide valuable information about the directionality of effects between passion and outcomes. Thus, harmonious and obsessive passions at Time 1 were significantly associated with the outcomes at Time 2, whereas the reverse (i.e., the association between the outcomes at Time 1 and the passions at Time 2) was not found. These findings support the fact that passion might be more of an antecedent than a consequence of work satisfaction, burnout, and perceptions of adaptive student behaviors. These findings are in line with past research that has shown that passion is implicated in a variety of personal and professional outcomes such as subjective well-being and vitality (Rousseau & Vallerand, 2003, 2008; Vallerand et al., 2006) and reduced depression, reduced anxiety, and positive affective experiences at work (Vallerand & Houlfort, 2003). Thus, additional research over a

longer period of time (e.g., a whole academic year) is needed to replicate the present findings.

Finally, much work remains to be done with respect to understanding the processes underlying the development of passion. Why is it that some teachers develop an obsessive passion toward teaching and others take the more beneficial road of harmonious passion? Work by Mageau et al. (in press) has suggested that an autonomy-supportive social environment (i.e., where choices are offered, initiatives are supported, and control is minimized) promotes the emergence of harmonious passion. Further research to clarify the antecedents of passion for teaching appears in order. Such research could result in important theoretical and applied advances, eventually leading to the creation of programs designed to facilitate the development of teachers' harmonious passion, which would be beneficial for teachers themselves and for their students.

### *On the Prevalence of Passion in the Teaching Realm*

An implication of the present research worth noting is that it empirically showed that passion for teaching appears to be highly prevalent. The hypothesis that a majority of teachers would be passionate toward their job was largely confirmed. Indeed, 93.1% of the teachers in the present sample met the criteria for at least a moderate level of passion toward teaching (Vallerand et al., 2003). These results confirm the widespread notion that teachers are passionate about their job (Day, 2004; Elliott & Crosswell, 2001; Fried, 1995; Nias, 1996) and highlight the relevance of studying passion in the teaching realm. Thus, our study fills an empirical gap by being the first to support the widely accepted claim that teachers are passionate. However, results about the prevalence of passion for teaching are limited to our sample. Thus, these results cannot be generalized to the broader population of teachers. Further research with a sample representative of the teaching population is clearly needed on this issue.

### *Limitations*

Although the results from the present study are consistent with a causal interpretation, the data are correlational in nature, and therefore, definitive conclusions about causality are not warranted. Future research using experimental designs should be used to replicate and confirm the proposed model. Another limitation to consider is that the coefficients of change—although statistically significant—were low ( $\beta$ s ranging from 0.11 to 0.22). This might be because of the short interval (i.e., 3 months) between the two measurement times that did not allow for much change to take place. This interpretation is supported by the stability coefficients that were rather high (see Figure 1). Therefore, interpretation of the present results should be done with caution. Clearly, subsequent research should use a longitudinal design extending over an entire school year to see whether the present results are replicated and whether higher coefficients of change might be obtained. Finally, we should underscore that the measure assessing student positive behaviors was completed by teachers. Thus, although the results showed that the more passionate the teachers, the more they perceived students to display adaptive behaviors, we cannot conclude that such a finding reflects actual positive student behaviors. Indeed, it is possible that changes in student behavior were because

of changes in teachers' perceptions. Therefore, in future research, it would be important for student behaviors to be reported by the students themselves or assessed by a third party (e.g., through videos), for objectivity concerns.

### Conclusion

In sum, the present findings provide interesting answers about the presence and role of passion in the teaching realm. Because harmonious passion promotes positive intrapersonal outcomes and relates to perceived student outcomes, future research is clearly needed to more completely understand the determinants of harmonious passion for teaching. Furthermore, interventions designed to promote a harmonious passion should also be the focus of future research. This would help teachers personally derive the best out of their teaching involvement while sustaining students' interest toward education.

## Appendix

### The Passion Scale—Adapted for Teaching

1. I spend a lot of time doing my job as a teacher.
2. I like my job as a teacher.
3. My job as a teacher is important for me.
4. My job as a teacher is a passion for me.
5. My job as a teacher is in harmony with the other activities in my life.
6. I have difficulties controlling my urge to do my job as a teacher.
7. The new things that I discover doing my job as a teacher allow me to appreciate it even more.
8. I have almost an obsessive feeling for my job as a teacher.
9. My job as a teacher reflects the qualities I like about myself.
10. My job as a teacher allows me to live a variety of experiences.
11. My job as a teacher is the only thing that really turns me on.
12. My job as a teacher is well integrated in my life.
13. If I could, I would only do my job as a teacher.

14. My job as a teacher is in harmony with other things that are part of me.
15. My job as a teacher is so exciting that I sometimes lose control over it.
16. I have the impression that my job as a teacher controls me.

# Athletic Classmates, Physical Self-Concept, and Free-Time Physical Activity: A Longitudinal Study of Frame of Reference Effects

Ulrich Trautwein

Max Planck Institute for Human Development

Erin Gerlach

University of Bern

Oliver Lüdtke

Max Planck Institute for Human Development

The systematic analysis of factors that promote or impede physical activity in children is an urgent task for educational researchers. The present study investigated the reciprocal relationship between physical self-concept, teacher-assigned grades in physical education classes, and free-time physical activity, and analyzed positive and negative consequences of being in a class with high class-average physical ability. Data from a large, representative sample of 1,095 preadolescents from 66 classrooms were examined within a longitudinal framework. Multilevel analyses showed that membership in a class with high class-average physical ability was associated with lower physical self-concept and free-time physical activity and highlighted the significant role of teacher-assigned grades in the development of physical self-concept and physical activity. Furthermore, as predicted, there were positive reciprocal effects between physical self-concept and physical activity levels.

**Keywords:** physical ability, physical activity, self-concept, frame of reference effects, teacher-assigned grades

Over the past decade, there has been increasing interest in the physical activity levels of preadolescents and adolescents. A growing percentage of children in Western industrialized countries are overweight, increasing their risk of developing several medical problems, including cardiovascular disease and Type II diabetes (Brettschneider & Naul, 2004; Strauss & Pollack, 2001). Moreover, many researchers (e.g., Biddle & Mutrie, 2001; Sonstroem, 1984) assume that physical activity is associated with positive psychological and behavioral outcomes in children, such as global well-being, social integration, personality maturation, and positive self-views. Not surprisingly, there is broad consensus among researchers, physicians, educators, and politicians that the physical activity levels of children and adolescents need to be increased (e.g., National Association for Sport and Physical Education, 2004). The systematic analysis of factors associated with physical activity in children is thus a critical task for educational and developmental research.

Prior research with adolescents and adults has found evidence for a positive association between physical self-concept and physical activity levels. The present study addresses the reciprocal relationship between physical activity and physical self-concept in preadolescents, focusing on two additional factors. First, we examined the role of class composition in terms of physical ability levels. In academic subjects, class composition has been shown to be associated with frame of reference effects. Because students compare their own ability with that of their classmates, students in high-ability classes typically report comparatively low self-concepts (Marsh, 1987). We examined whether such frame of reference effects are also found in the physical domain, asking whether classmates' physical ability level is associated with individual physical self-concept and physical activity levels. Second, we sought to explore whether teacher-assigned grades account for any frame of reference effects found.

## Physical Self-Concept, Physical Ability, and Physical Activity in Children

In recent years, there has been an increasing awareness of the predictive effects of a student's self-concept for his or her feelings, motivation, activities, and achievement in various academic and nonacademic domains (e.g., Eccles, Wigfield, & Schiefele, 1998; Harter, 1998; Marsh, Trautwein, Lüdtke, Köller, & Baumert, 2005; Trautwein, Lüdtke, Köller, & Baumert, 2006). The self-concept is a person's evaluation of his or her own qualities and standing in general or in specific domains. Students' self-concepts are typically measured via self-report measures (e.g., Byrne, 1996). In the developmental and educational literature, conceptions that center on global self-evaluations (e.g., "All in all, I am inclined to feel

that I am a failure"; Rosenberg, 1965) have gradually been replaced by models that focus on domain-specific self-evaluations (e.g., Marsh & Shavelson, 1985; Shavelson, Hubner, & Stanton, 1976) instead of or in addition to the global component. Typical domain-specific self-concept items are "I am quite good at mathematics" (math self-concept), "I have a poor vocabulary" (verbal self-concept), and "I'm talented when it comes to sports" (physical self-concept). Domain-specific academic self-concepts reflect a person's self-evaluation regarding a specific academic domain or ability and have been shown to be more closely related to academic outcomes than more global self-beliefs (e.g., Marsh, Trautwein, Lüdtke, Köller, & Baumert, 2006).

The conception of self-concept is related to the conception of self-efficacy beliefs (Bandura, 1997) but is not identical (Bong & Skaalvik, 2003). Whereas self-efficacy measures typically require a context-specific, goal-referenced evaluation of competence (e.g., "I am able to get an A on my next math test"), self-concept measures tap a person's generalized beliefs about his or her competence using normative statements.

Physical self-concept is known to be an important part of the self-definition in childhood (e.g., Bohrnstedt & Felson, 1983; Harter, 1998), and research has documented statistically significant relations between physical self-concept and physical ability (e.g., Sonstroem, 1997; Wigfield et al., 1997). In a recent study with 376 students in Grades 7, 8, and 9, Marsh, Chanal, and Sarrazin (2006) collected gymnastics self-concept and performance measures before (Time 1) and after (Time 2) a 10-week high school gymnastics program. As predicted by the authors, when performance at Time 1 was controlled, gymnastics self-concept positively predicted later performance to a statistically significant degree (standardized regression coefficient of  $\beta = .15$ ); when Time 1 gymnastics self-concept was controlled, gymnastics performance positively predicted later gymnastics self-concept ( $\beta = .15$ ). In other words, gymnastics performance and gymnastics self-concept were reciprocally related. At a casual glance, these effects may seem to be of moderate size. However, beta coefficients for cross-lagged effects (i.e., effects of one variable measured at an earlier time point on another variable measured at a later time point) in the range of .10 to .15 are common in real-world, nonexperimental longitudinal research on personal characteristics and can be considered meaningful (e.g., Roberts, Caspi, & Moffitt, 2003). When interpreting such cross-lagged effects, it is important to bear in mind that changes in physical self-concept, physical activity, and physical abilities are, of course, multiply determined (Ahadi & Diener, 1989) and that cross-lagged effects are potentially cumulative over time: The specific effect of a small beta coefficient may be quite substantial if it continues over extended periods of time (Neyer & Asendorpf, 2001; Prentice & Miller, 1992).

Furthermore, physical self-concept is closely related to the time and effort that people of all ages invest in sport and exercise (for summaries, see Biddle & Mutrie, 2001; Marsh, 2002; Sonstroem, 1997). For instance, in a study of contextual motivation in physical education, Standage, Duda, and Ntoumanis (2003) found the perceived physical competence of the 328 participants (mean age = 13.56 years) to be closely associated with their intention to engage in leisure-time physical activity in the near future ( $r = .46$ ). According to Cohen's (1988) classification of correlation coefficients, this constitutes a moderate to large association. Physical

self-concept also emerged as an important predictor of physical activity in a sample of about 1,500 Grade 6 students examined by Eccles and Harold (1991). In this study, physical self-concept correlated with free time spent on sport ( $r = .47$  for girls and  $r = .44$  for boys). In fact, the correlation between physical self-concept and free-time involvement in sport was significantly higher than the correlation between math or English self-concept and free-time involvement in math or English. Marsh, Papaioannou, and Theodorakis (2006) studied reciprocal effects of physical self-concept and exercise behavior at the beginning (Time 1) and end (Time 2) of the school year in a large sample of 2,786 students from 200 physical education classes at different levels of schooling. When initial exercise behavior was controlled, physical self-concept statistically significantly predicted Time 2 exercise behavior (standardized regression weight of  $\beta = .17$ ), and exercise behavior statistically significantly predicted Time 2 self-concept ( $\beta = .10$ ).

### Frame of Reference Effects, Self-Concept, and Physical Activity

The association between frame of reference effects, physical self-concept, and physical activity is of specific interest in the present study. There is now abundant evidence to show that the development of students' domain-specific self-concepts in the academic domain is considerably associated with the achievement of others in their immediate environment (Marsh & Craven, 2002; Marsh, Trautwein, Lüdtke, Baumert, & Köller, 2007; Trautwein, Lüdtke, Marsh, Köller, & Baumert, 2006). Individuals tend to focus on people close to them when constructing their frames of reference for social comparisons (Skaalvik & Skaalvik, 2002; Tesser, 1988). Very often, classmates or colleagues provide the frame of reference.

In many developmental and educational contexts, frame of reference effects result in students developing comparatively low self-concepts in high-achieving groups and comparatively high self-concepts in low-achieving groups. Rather than forming an impression of their own abilities in comparison with a "typical student" of their own age, students focus on their immediate environment. Extending earlier work by Davis (1966; see also Schwarzer, Lange, & Jerusalem, 1982), Marsh (1984, 1987) coined the term "big-fish-little-pond effect" (BFLPE) to describe this finding. Figure 1a illustrates the assumptions of the BFLPE. Academic self-concept is assumed to be positively related to individual achievement (high-achieving students will have higher academic self-concepts than low-achieving students), but negatively related to school- or class-average achievement (the same students will have lower academic self-concepts in a class where the average achievement is high and higher academic self-concepts in a class where the average achievement is low). Extensive empirical support for this effect has been accumulated over the last two decades (e.g., Lüdtke, Köller, Marsh, & Trautwein, 2005; Marsh & Hau, 2003; Marsh, Köller, & Baumert, 2001). Unfortunately, in contrast to the statistical significance of the predictor variables, the effect sizes for class- or school-level effects have received little attention.

Does the BFLPE generalize to the physical domain? On the one hand, it seems plausible to assume that the mechanisms governing the development of academic self-concepts also apply to physical self-concept. In fact, relative to other subjects, there may be a

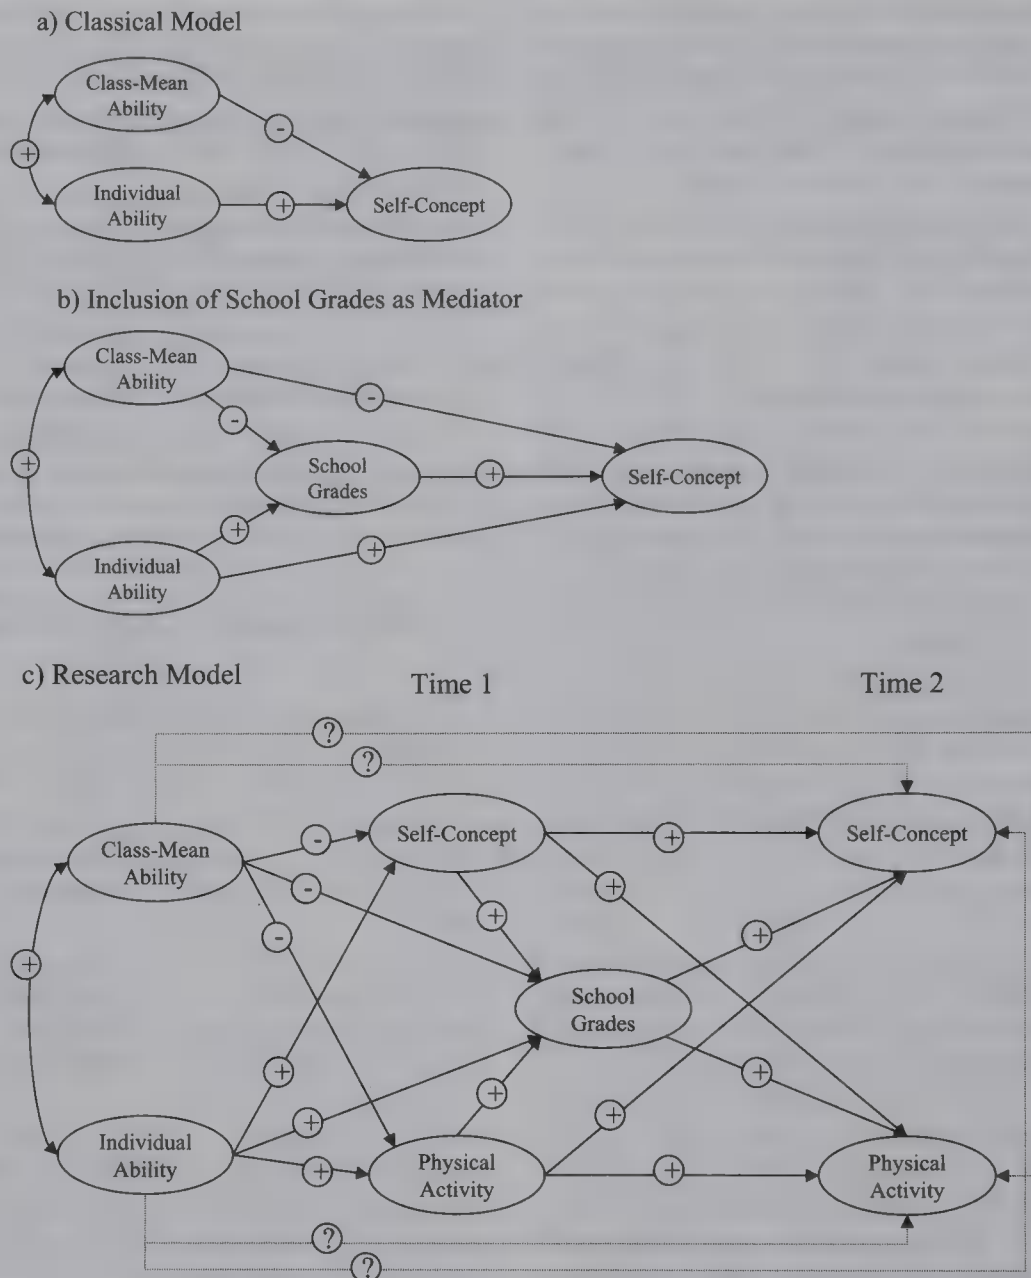

Figure 1. A schematic depiction of the big-fish-little-pond effect.

comparatively rich basis for social comparison in the physical domain. Students' abilities in the physical domain are more visible to their classmates than performance on a mathematics test, for example. Whereas students' oral contributions to lessons often provide the only direct basis for social comparison in mathematics (grades for written work typically are not directly accessible), performance in physical education (PE) lessons is always in the public sphere and may well elicit direct social comparisons (e.g., in athletics, team sports, or return matches). Moreover, it is common for ability rankings to be made explicit in PE lessons; for example, when teams are picked. It is still standard practice in many schools for teams to be selected by a process of peer nomination in PE lessons. Taken together, the specific features of PE lessons may reinforce the effects of social comparison processes.

On the other hand, physical self-concept is also more likely to be influenced by out-of-school factors than, say, mathematics or English self-concept. In addition, many sports involve improvement in an activity over time (e.g., running faster, jumping higher,

hitting a ball further); such improvements occur on an absolute metric and do not depend on external feedback. Clearly, out-of-school comparison as well as improvements in physical ability that can be evaluated on an absolute standard may counteract school-based social comparison processes.

It is interesting that, despite their theoretical and practical relevance, frame of reference effects on physical self-concept have remained virtually untested. As far as we are aware, the first study to investigate the BFLPE in the physical domain using the classical regression-based paradigm was reported by Chanal, Marsh, Sarrazin, and Bois (2005). These authors performed multilevel modeling with the responses of 405 Grade 7 and Grade 9 students from 20 groups participating in a 10-week gymnastics program. In line with the predictions of the BFLPE, individual achievement positively predicted gymnastics self-concept, whereas group-average gymnastics skills had a negative effect on gymnastics self-concept. Hence, the Chanal et al. (2005) study provides initial evidence that the BFLPE also holds in the context of physical education.

## Performance, Performance Feedback, and Frames of Reference

According to the theoretical assumptions of the BFLPE (e.g., Marsh & Craven, 2002), day-to-day social comparison with other students contributes to the emergence and development of the frame of reference effects that are encapsulated in the negative regression weight from class-average ability on self-concept. One of the greatest challenges to the BFLPE is the alternative hypothesis that the effect is not a consequence of social comparison processes, but simply mirrors teachers' grading practices (see Marsh, 1987; Trautwein & Lüdtke, 2005). This alternative explanation of the BFLPE rests on two assumptions: first, school grades—and not social comparison processes—are the main factor in self-concept development; second, average school grades are comparable in most schools, yielding similar average self-concepts despite diverging ability scores. Is there empirical support for this alternative explanation of the BFLPE?

Clearly, teacher-assigned grades are of pivotal importance for students' self-concepts (see Hansford & Hattie, 1982; Skaalvik & Skaalvik, 2002). Teacher-assigned grades provide students with transparent, relevant feedback and can directly impact their academic careers. Research has shown not only that grades impact students' self-concepts (e.g., Marsh et al., 2005; Valentine, DuBois, & Cooper, 2004), but also that academic self-concepts impact later grades (e.g., Trautwein, Lüdtke, Köller, & Baumert, 2006).

Grading practices may vary considerably within a school (Willingham, Pollack, & Lewis, 2002). One specific form of this variation is the "grading-on-a-curve" effect, which occurs when most teachers assign the best-performing student in the class a very good or good grade and the poorest-performing student a D or E grade. In this case, grades are assigned on a norm-referenced basis rather than a criterion-oriented basis (Marsh, 1987). Grading-on-a-curve effects are likely to vary across states and countries. In some countries, they are very large. For instance, in their study with more than 14,000 students from 621 schools in Germany, Trautwein, Lüdtke, Marsh, et al. (2006; Study 1) found an intra-class correlation coefficient (see Snijders & Bosker, 1999) of .63 for achievement in a standardized mathematics test. This means that 63% of the variance in mathematics achievement was explained by membership in different schools, indicating that the average achievement varied considerably across schools. In contrast, the intraclass correlation coefficient for teacher-assigned mathematics grades was only .05, indicating that the average teacher-assigned grade was remarkably similar across schools.

When teachers grade on a curve, the grades awarded only partially reflect students' objective academic standing. Given that students' academic self-concepts are markedly influenced by their grades, grading on a curve might introduce or reinforce the frame of reference effect postulated in the BFLPE model. Hence, grades are potentially a key mediator variable between individual and school-average achievement, on the one hand, and student motivation, on the other. This possibility is illustrated in Figure 1b. Whereas high individual achievement has a positive effect on school grades, high class-average achievement has a negative effect. In other words, students in classes with high average achievement receive lower grades for the same work. Grades, in turn, predict self-concept.

It is interesting that, despite their potential to reinforce the BFLPE, the role of school grades has rarely been systematically investigated. One exception is a study reported by Marsh (1987), who examined the association between school grades (GPA) and academic self-concepts in a sample of 2,213 grade 10 boys from 87 high schools. In this study, GPA significantly predicted academic self-concept and partially mediated the effect of individual achievement. The predictive effect of class-average achievement was only slightly affected by including GPA in the analyses. A particularly strong effect of school grades was reported by Trautwein, Lüdtke, Marsh, et al. (2006), who found mathematics school grades to have the single most important predictive effect on mathematics self-concept. However, the effects of individual and school-average mathematics achievement were only partly mediated by school grades.

Taken together, these two studies highlight the important role of school grades, but also point to frame of reference effects that cannot be fully explained by grading-on-a-curve effects. Better tests of the hypothesis that the BFLPE is strongly reinforced by grading practices are evidently needed; the present study attempts to provide such a test.

## The Present Investigation

At Time 1, a sample of 1,095 Grade 3 students from 66 classes participated in a test of physical fitness and completed questionnaires about their physical self-concept and free-time physical activity. At Time 2, approximately 15 months later, the same students again completed the questionnaire measures. The students were assigned their first grades for PE in the interval between Time 1 and Time 2.

Figure 1c illustrates the central assumptions of our research model. Our first set of hypotheses concerns frame of reference effects on physical self-concept and physical activity before and after the preadolescents in our sample were first given teacher feedback on their physical performance in the form of PE grades. We formulated three hypotheses in this regard. One, controlling for individual physical ability, we expected to find a negative predictive effect of class-average physical ability on students' physical self-concepts. Two, assuming that grading-on-a-curve effects were observable in our sample, we expected the negative predictive effect of class-average physical ability to be larger at Time 2, when PE grades had been awarded for the first time. Three, we tested for frame of reference effects with regards to physical activity. When their own physical ability is controlled, do students placed in a class with high class-average physical ability report more or less free-time physical activity? Both outcomes seem plausible. A student who considers most of her classmates to be better at PE might decide not to compete with them in that discipline, but to work hard on, say, mathematics. At the same time, the more athletic students there are in the class, the more likely it is that a student will be invited to join a sports club for social reasons. Against this background, our hypothesis of a negative relation between class-average physical ability and free-time physical activity was somewhat tentative.

Our second set of hypotheses concerned possible frame of reference effects on school grades. Given the evidence for grading-on-a-curve effects recently reported by Trautwein, Lüdtke, Marsh, et al. (2006; Study 1), we expected class-average physical ability

to negatively predict PE school grades: Students with the same physical ability were expected to receive lower grades when placed in a high-ability class than when placed in a low-ability class.

Our third set of hypotheses targeted the reciprocal relationship between physical self-concept and physical activity. We expected to find positive predictive effects of Time 1 physical self-concept on Time 2 physical activity and of Time 1 physical activity on Time 2 physical self-concept, when controlling for the respective Time 1 variables. At the same time, we hypothesized that these predictive effects would be largely mediated by PE grades.

Finally, we used gender and body fat (as indicated by the body mass index [BMI]) as additional predictor variables in all sets of analyses. These variables were mainly used as control variables. Based on the work by Eccles and Harold (1991; see also Marsh, 1993), we expected boys to report higher physical self-concepts and more free-time involvement in sports than girls. Furthermore, we expected body fat to have a negative impact on self-concept and physical activity; however, we were especially interested in whether BMI would have any effect on physical self-concept and activity when the actual performance level was controlled.

## Method

### Sample and Procedure

The data considered here derive from the Sport Involvement and Development in Children study conducted at the University of Paderborn, Germany (see Brettschneider & Gerlach, 2004, for more information). The present study draws on data collected from about one third of all Grade 3 students in the city of Paderborn (about 140,000 inhabitants), attending a total of 66 classes in 22 schools. Students in Germany are required to attend the elementary school located closest to the family's place of residence. To ensure that the sample was highly representative, schools were randomly selected for participation.

At Time 1 (T1; spring 2001), 1,185 Grade 3 students (50.7% female) were administered a physical ability test and a written questionnaire. The mean age at T1 was  $M = 9.67$  ( $SD = 0.64$ ). Approximately 15 months later (T2; summer 2002), the same children were re-contacted and asked to complete the questionnaire again. A total of 1,095 students (94.8% of the original sample) participated at T2. These 1,095 students represent the basis for the current study. The students who participated at both time points did not differ from those who dropped out in terms of physical ability, body fat, age, or gender (all  $ps > .10$ ). A statistically significant, albeit small, difference was found for physical self-concept, with dropouts ( $M = 3.27$ ,  $SD = 0.67$ ) reporting a higher physical self-concept than continuers,  $M = 3.11$ ,  $SD = 0.65$ ;  $t(1, 183) = 2.25$ ,  $p < .05$ , Cohen's  $d = 0.24$ .

The vast majority of participating students were Caucasian (>95%) and had German citizenship (83.8%). Children with Russian (6.7%) and Turkish citizenship (2.2%) were the largest minority groups. We computed the weight status of all participants using the German guidelines on obesity in childhood and adolescence (Kromeyer-Hausschild et al., 2001; for international guidelines see Cole, Bellizzi, Flegal, & Dietz, 2000). According to these guidelines, 76.2% of the students fell into the normal weight range, 12.4% were underweight, 7.4% were overweight, and 4.0% were obese.

In all classes, trained research assistants (mostly college students majoring in PE) administered the physical ability test during regular PE lessons. PE is a compulsory element of the elementary and high school curriculum in Germany; only students with severe chronic health issues that preclude participation are permanently excused from classes. All students in PE classes were required to participate in the physical ability test as part of a citywide program to survey the athletic abilities of elementary school children.

The questionnaire part of the study was administered in regular school hours within 9 weeks of the physical ability test. To guarantee high quality of the data collected, trained research assistants (university students) administered the questionnaire to small groups of about 6 students. Students were encouraged to ask for help if they did not understand a question.

### Instruments

*Standardized test of basic physical ability.* At T1, students' overall physical ability was tested by means of the Hagedorn Obstacle Course (Riepe & Zindel, 1999), a standardized test of physical coordination, balance, and speed. This parsimonious test measures complex coordination skills using apparatus to be found in any (German) sports hall. It has been externally validated by trainers, who provided expert ratings of various aspects of performance (e.g., flow of movement, appropriate use of strength, anticipation of the individual stations of the course). The course consists of a slalom, a balancing exercise, a forward roll, and getting over and through obstacles. Students completed the test twice; the average time needed to complete the course was taken as the student's physical ability score. To facilitate interpretation, physical ability scores were reverse scored such that higher scores indicate better physical skills. The validity of students' scores on this ability test is supported by significant correlations with observer ratings and other measures of physical fitness. In the present sample, for instance, the correlation with school PE grades was  $r = .44$  ( $p < .001$ ). In addition, physical ability test scores were associated with teachers' overall evaluation of the students' physical ability ( $r = .47$ ,  $p < .001$ ) and with BMI ( $r = -.41$ ;  $p < .001$ ).

*School grades.* At T2, students reported the PE grade they had been awarded at the end of Grade 3 using the six-level grading system implemented throughout Germany. We reverse coded these grades to produce the following six levels: *excellent* (6), *good* (5), *satisfactory* (4), *sufficient* (3), *poor* (2), and *very poor* (1).

*BMI.* The BMI is the measure most widely used to tap the percentage of body fat. The BMI is calculated by the formula

$$BMI = \frac{\text{weight}}{\text{height}^2},$$

where weight is measured in kilograms and height in meters. In the present study, height and weight were measured by trained research assistants.<sup>1</sup>

*Physical self-concept.* Five items from a German adaptation of the physical self-concept scale from Harter's (1985) Self Perception Profile for Children were administered ("I am very good at

<sup>1</sup> In preliminary analyses, the predictive power of the BMI was compared with a score that was standardized separately for boys and girls. The patterns of relations with the other variables under investigation proved to be almost identical in both approaches. We therefore used the original BMI approach.

sport"; "I learn quicker than others of my age in sport"; "I learn new exercises very quickly in sport"; "I am as good as others of my age in sport"; "I am just not good at sport") with a 4-point response format (ranging from 1 = *disagree* to 4 = *agree*). Internal consistency (Cronbach's  $\alpha$ ) was .76 at T1 and .83 at T2.

**Physical activity.** In Germany, all elementary and high school students have up to 3 hr of compulsory PE classes per week. These classes are taught by regular teachers, typically in the school's sports hall. Other than these regular PE classes, elementary schools offer limited opportunities for students to engage in physical activity. Rather, most physical and sports activities are organized by independent sports clubs (*Vereine*). These nonprofit organizations offer a variety of individual and team sports and are usually supported by the local authorities (which provide sports facilities and equipment) and the German Olympic Sport Federation. At both points of measurement, students reported how many hours they typically dedicated to physical activity at a sports club (*Verein*) for each day of the week separately. This response format has been shown to yield more reliable estimates than more global reports (e.g., Schwarz & Oyserman, 2001; Tourangeau, Rips, & Rasinski, 2000). Each student's responses were summed across the 7 days of the week to form an overall index of free-time physical activity.

### Statistical Analyses

We performed multilevel regression analyses to predict physical self-concept and physical activity at T1 and T2. In most studies conducted in schools, individual student characteristics are confounded with classroom or school characteristics because individual students are not randomly assigned to groups. This clustering effect introduces problems related to appropriate levels of analysis, aggregation bias, and heterogeneity of regression (Raudenbush & Bryk, 2002). For the present investigation, it is particularly important to note that the meaning of a variable at the student level may not bear any straightforward relation to its meaning at the classroom level. The negative BFLPE represents a dramatic example of this problem, in that achievement at the individual level is positively related to self-concept, whereas achievement at the class-average level may be unrelated or negatively related to self-concept. The juxtaposition of the effects of individual achievement and class-average achievement is inherently a multilevel issue that cannot be represented properly at either the individual or the classroom level. Particularly when major variables represent different levels, it is important to analyze data with appropriate multilevel statistical procedures. Multilevel modeling, a special form of regression analysis, provides a powerful methodology for handling hierarchical data and was used in this study. A detailed presentation of multilevel modeling (also referred to as hierarchical linear modeling; HLM) is beyond the scope of the present investigation and is available elsewhere (e.g., Raudenbush & Bryk, 2002; Snijders & Bosker, 1999).

In the present study, all multilevel analyses were computed using the computer program HLM 6 (Raudenbush, Bryk, Cheong, & Congdon, 2004). We specified three-level models, with students as the first level, classes as the second level, and schools as the third level. Predictor variables were included at Level 1 and Level 2 only; we decided to include class-average physical ability but not school-average physical ability in these analyses for three reasons

(for a similar rationale, see Trautwein, Lüdtke, Marsh, et al., 2006, Study 2). First, the correlation between class-average and school-average physical ability amounted to .79, yielding highly redundant information at the two levels; accordingly, multicollinearity would result if both variables were considered simultaneously. Second, from a theoretical point of view, class-average ability is more central to self-concept development and physical activity levels, given that it provides the most immediate frame of reference. Third, in hierarchical linear modeling, variables at lower levels can explain variance at higher levels, but not vice versa; hence, when class-average ability is included, this variable could also explain school-level differences that may exist.

To test our hypotheses (see above and Figure 1c), we specified several sets of multilevel models using HLM 6. As in ordinary regression analyses, one outcome variable was regressed on several predictor variables in each of these models. By specifying several consecutive models, researchers are able to observe the change in the predictive power of one variable when an additional variable is included. In this way, the associations between variables in a path model as well as mediator hypotheses such as that specified for PE grades can be tested within the framework of HLM. There are two main differences between our approach and typical studies using a structural equation modeling approach. First, multilevel regression analysis cannot test mediator hypotheses in a single step, but rather specifies a set of models; second, our analyses are based on manifest indicators and not on latent constructs.

HLM does not report standardized regression coefficients. To enhance the interpretability of the regression coefficients produced, we standardized ( $M = 0$ ,  $SD = 1$ ) all continuous variables before performing the multilevel analyses. Dichotomous variables were retained in their original metric. Physical ability was aggregated at the class level to form an index of the overall level of physical ability in the class (and was not restandardized). All models reported are random-intercept models estimated by the full maximum likelihood method. We assessed model fit using the deviance values provided by HLM, which can be regarded as a measure of lack of fit between model and data (Snijders & Bosker, 1999). Deviance values are not usually interpreted directly; rather, differences in deviance values are calculated for several models for the same data set. The difference in deviance between two models has a chi-square distribution with degrees of freedom equal to the difference in the number of parameters estimated. Because we used the full maximum likelihood method, the chi-square statistic can be used to evaluate the change in model fit when either a fixed or a random effect is added. Large values of the chi-square statistic indicate that the model with more estimated parameters provides a better fit to the data than the more parsimonious model.

Effect sizes have found increasing use in educational research. The statistical significance of a finding says little about its substantive meaning or real-world importance (see Kline, 2004; Nickerson, 2000). Effect sizes allow the meaningfulness of an empirical result to be presented clearly and the findings of empirical studies to be more readily appreciated; they also help politicians and policy makers in their decision making (McCartney & Rosenthal, 2000; for a recent overview of effect sizes, see Grissom & Kim, 2005).

How can the meaningfulness of results from multilevel modeling be determined? In our study, we used three indicators of effect

size. First, in analogy to the measure of explained variance in ordinary linear regression models, we report the overall proportion of variance explained by the predictor variables for each model. This measure is determined by calculating the proportion of the total variance that is reduced when the predictor variables are introduced into the specific model (see Snijders & Bosker, 1999).

Second, we report easily interpretable regression coefficients for Level 1 variables. Because we standardized all continuous Level 1 predictor and outcome variables before entering them in our multilevel models, the coefficients of the continuous Level 1 variables can be interpreted in almost the same way as the standardized regression coefficients resulting from ordinary regression analysis. With reference to Cohen's (1988) suggestions for correlations, we consider a regression coefficient of 0.10 to mark the lower bound for a meaningful effect (for a similar rationale, see Roberts et al., 2003). Because gender was not standardized, the regression coefficients for gender show the differences in girls' and boys' outcome variables in standard deviations, controlled for the other predictor variables.

Third, in line with the majority of previous multilevel research (e.g., Marsh & Hau, 2003), we did not restandardize our Level 2 predictor variable (class-average physical ability). Hence, the class-level regression weights show change in the dependent variable (physical self-concept/activity) corresponding to an increase of one unit in class-average physical ability, expressed in the metric of physical ability at the student level. Tymms (2004) proposed that the effect size for continuous Level 2 predictors in multilevel models, which is comparable with Cohen's  $d$ , be calculated using the formula:

$$\Delta = 2 \times B \times SD_{\text{predictor}} / \sigma_e$$

where  $B$  is the unstandardized regression coefficient in the multilevel model,  $SD_{\text{predictor}}$  is the standard deviation of the predictor variable at the class level, and  $\sigma_e$  is the residual standard deviation at the student level. The resulting effect size describes the difference in the dependent variable between two classes that differ by two standard deviations on the predictor variable. Given the important role of physical activity for lifetime health and the association between physical self-concept and overall self-esteem, even a small impact of the class composition should be of interest to researchers and practitioners. We thus suggest that an effect size of  $\Delta \geq 0.20$  can be considered of practical significance in the present research.

## Results

### *Physical Self-Concept and Physical Activity: Descriptive Results*

Overall, students reported rather positive physical self-concepts at T1 ( $M = 3.11$ ,  $SD = 0.65$ ) and T2 ( $M = 3.04$ ,  $SD = 0.67$ ). The moderate decrease between T1 and T2 was statistically significant,  $t(1094) = 3.66$ ,  $p < .001$ ,  $d = 0.11$ , and is in line with research showing that self-concepts decline over the preadolescent years (e.g., Wigfield et al., 1997). Average BMI at T1 was 17.37 ( $SD = 2.94$ ). The correlation between T1 and T2 physical self-concept was  $r = .58$  ( $p < .001$ ). At both measurement points, the majority of students (T1: 57.3%; T2: 59.1%) reported attending sport clubs at least once a week. The average free time that these students

reported dedicating to sport amounted to  $M = 2.34$  hr per week ( $SD = 1.65$ ) at T1 and  $M = 2.39$  hr per week ( $SD = 1.78$ ) at T2. Overall mean free-time physical activity did not differ between T1 and T2,  $t(1094) = -0.74$ ,  $ns$ . The correlation between T1 and T2 physical activity was  $r = .47$  ( $p < .001$ ).

### *Predicting T1 Physical Self-Concept and Physical Activity: Evidence for the BFLPE*

Our first research question addresses frame of reference effects on physical self-concept and physical activity. Do the data indicate a BFLPE on the physical self-concepts of preadolescents before they are awarded their first PE grades? To answer this question, we first analyzed whether there was a difference in the average ability level of students in different classes by specifying an empty model in HLM. An empty model includes only the outcome variable, but no predictor variables, and indicates whether the mean of the outcome variable differs meaningfully across classes or schools. This was indeed the case: More than 15% of the total variance was located at the class or school levels.

We next used T1 physical self-concept as the dependent variable. Table 1 reports the results of these analyses. In model M1, we specified the classical BFLPE model as illustrated in Figure 1a by including both individual physical ability scores and class-average physical ability scores as predictor variables. As documented in Table 1, individual physical ability positively predicted physical self-concept; the regression coefficient of  $B = 0.45$  indicates that an increase in the ability score of one standard deviation was associated with an increase in physical self-concept of almost half a standard deviation. The statistically significant regression coefficient for class-average physical ability was  $B = -0.39$ . We calculated the effect size for this coefficient using the formula described above. With a standard deviation in class-average ability of  $SD = 0.44$  and a residual standard deviation at the student level of  $\sigma_e = 0.92$ , we found a small effect:

$$\Delta = 2 \times (-0.39) \times 0.439 / 0.92 = -0.37.$$

Hence, students with the same ability levels had higher physical self-concepts if they were in a class with low average ability than if their class showed high average ability. The overall percentage of variance explained amounted to 0.16. The model fit of model M1 was statistically significantly better than the fit of an empty model with physical self-concept as the dependent variable,  $\chi^2 = 191$ ,  $df = 4$ ,  $p < .001$ .<sup>2</sup>

In M2, we tested for the effects of gender and BMI. Because BMI and physical ability were meaningfully associated, we removed physical ability to estimate the unique effect of gender and BMI. As expected, both variables negatively predicted physical self-concept, but the percentage of explained variance was lower than in M1. M3 is a combination of M1 and M2, including ability as well as gender and BMI. The regression coefficients for indi-

<sup>2</sup> We additionally specified random effects for the impact of class-average achievement at the school level in model M1 as well as in models M4, M7, M10, and M14 to check whether class-average physical ability had the same effect on the outcome variables in all 22 schools. For all these analyses, the variance components were statistically nonsignificant (all  $ps > .10$ ).

Note. *B* = unstandardized regression coefficient; *SE* = standard error of *B*; BMI = Body Mass Index.

\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

vidual and class-average achievement decreased slightly relative to M1 when gender and BMI were entered at the same time. Whereas the predictive effect of gender remained significant (with male students reporting higher physical self-concepts) despite a decrease in the beta weight, BMI did not prove to have an independent predictive effect on physical self-concept after controlling for gender and ability. A total of 18% of the variance was explained in model M3. A comparison of M3 and M1 indicated that model fit of M3 was statistically significantly higher than that of M1,  $\chi^2 = 19$ ,  $df = 2$ ,  $p < .001$ .

Taken together, we found support for the predictions of the BFLPE in this sample of preadolescent students. It is important to note that participants in the present sample had not yet received school grades on their performance in PE; hence, the results cannot be attributed to grading effects.

We next applied the same approach to check for frame of reference effects on physical activity. In models M4 to M6, T1 free-time physical activity was used as the dependent variable instead of physical self-concept. In M4 (see Table 1), physical ability test scores at the individual and class levels were used as predictors. This model examines whether the frame of reference effect is restricted to physical self-concept (see M1) or also applies to physical activity. Results showed that individual physical ability was indeed associated with higher physical activity, whereas the class-average ability level negatively predicted physical activity. Students with the same physical ability reported less free-time physical activity when placed in high-ability classes. With a standard deviation in class-average ability of  $SD = 0.44$  and a residual standard deviation at the student level of  $\sigma_e = 0.96$ , we found an effect size of

$$\Delta = 2 \times (-0.30) \times 0.439/0.96 = -0.27.$$

Relative to the empty model with a deviance of 3,088 ( $df = 4$ ), the model fit of M4 was clearly improved,  $\chi^2 = 28$ ,  $df = 2$ ,  $p < .001$ .

When the ability indicators were substituted by gender and BMI (see M5), only gender significantly predicted physical activity. In accordance with findings of Eccles and Harold (1991), female students reported less physical activity than male students did. In M6, the ability variables as well as gender and BMI were used as predictors. In this analysis, the gender effect was somewhat

smaller than in M5. The regression coefficients for individual and class-average physical ability were of the same magnitude as in M4. The model fit of M6 was statistically significantly higher than that of M4,  $\chi^2 = 11$ ,  $df = 2$ ,  $p < .01$ . Controlling for the other predictor variables in M6, the effect size for class-average physical ability was  $\Delta = -0.27$ . In sum, frame of reference effects were not restricted to the physical self-concept, but also applied to free-time levels of physical activity.

### Predicting PE Grades

We next performed a set of analyses to predict PE grades. As illustrated in Figure 1b, we predicted that students with the same ability levels would be assigned lower grades in classes with high class-average physical ability than in classes with low class-average physical ability; that is, we expected to find evidence for grading on a curve. The results of these analyses are shown in Table 2. In model M7, individual and class-average physical ability were used as predictor variables. Individual physical ability positively predicted PE grades, whereas class-average physical ability had a negative predictive effect. The regression coefficient of  $B = -0.40$  corresponds to an effect size of  $\Delta = -0.42$ . Relative to an empty model with PE grades as dependent variable, the model fit of M7 was clearly improved,  $\chi^2 = 299$ ,  $df = 2$ ,  $p < .001$ . In model M8, gender and BMI were additionally introduced. Controlling for physical ability at the individual and class level, there was a small gender effect in favor of girls. BMI did not significantly predict PE grades.

Finally, in M9, we included T1 physical self-concept and physical activity as additional predictor variables. M9 tests the predictive effects of the T1 predictor variables on PE grades (see left to middle part of the research model in Figure 1c). The analysis showed that—given the same physical ability scores at T1—students' physical self-concept and free-time physical activity positively predicted their PE grades in a statistically significant way. With regression weights of  $B = 0.16$  and  $B = 0.11$ , however, the predictive effect of these two variables was considerably smaller than the predictive effect of the physical ability test score. When the additional predictor variables were included, class-average ability still statistically significantly predicted teacher-assigned

Table 2  
Predicting Teacher-Assigned PE Grades: Results From Multilevel Modeling

Predictors	M7		M8		M9

Note. PE grade = physical education school grade; B = unstandardized regression coefficient; SE = standard error of B; BMI = Body Mass Index.  
\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

grades, and the effect size was  $\Delta = -0.32$ . The model fit of M9 was a considerable improvement on that of M8,  $\chi^2 = 63$ ,  $df = 2$ ,  $p < .001$ .

#### Predicting T2 Physical Self-Concept and T2 Physical Activity

The last two sets of analyses were performed with T2 physical self-concept and T2 free-time physical activity as the outcome variables (see Figure 1c). We expected frame of reference effects to be visible in T2 physical self-concept and T2 physical activity, but we expected these effects to be greatly reduced or eliminated when the corresponding T1 variables were included. Moreover, we expected to observe a reciprocal relationship between physical self-concept and physical ability. In addition, we speculated that PE grades would function as a mediator variable between physical self-concept and physical activity. To test these predictions, we

used the well-established procedure of specifying a sequence of multilevel models in which additional predictor variables are included one after the other. The logic of the sequence follows our research model illustrated in Figure 1c.

In M10 (see Table 3), the BFLPE was replicated with T2 physical self-concept as the outcome variable instead of T1 physical self-concept as in M1. Individual ability positively predicted T2 physical self-concept. The regression coefficient amounted to 0.56, which was slightly higher than the corresponding coefficient in M1. Similarly, the regression coefficient for class-average physical ability amounted to -0.50, compared to -0.39 in M1, even though the ability measure was administered about 15 months before the T2 self-concept measure. With a residual standard deviation at the student level of  $\sigma_e = 0.86$ , the effect size for class-average physical ability amounted to  $\Delta = -0.51$ , which can be considered a moderate effect size. Relative to the empty model,

Table 3  
Predicting T2 Physical Self-Concept and T2 Physical Activity: Results From Multilevel Modeling

Predictors	T2 physical self-concept								T2 physical activity

df	6		8		10		11		6		8		10		11	

Note. B = unstandardized regression coefficient; SE = standard error of B; BMI = Body Mass Index; PE grade = physical education school grade.  
\*  $p < .05$ . \*\*  $p < .01$ . \*\*\*  $p < .001$ .

the model fit of M10 was much higher,  $\chi^2 = 314$ ,  $df = 2$ ,  $p < .001$ . Overall, M10 indicates that the relevance of frame of reference effects with respect to physical self-concept increased between T1 and T2.

In M11, we additionally included T1 physical self-concept and T1 physical activity as predictor variables. As illustrated in Figure 1c, we expected the effects of individual and class-average physical ability on T2 physical self-concept to be mediated considerably by T1 physical self-concept and T1 physical activity to have an independent predictive effect on T2 physical self-concept. In line with our expectations, T1 physical self-concept positively predicted T2 physical self-concept. The coefficient of 0.44 indicates moderate stability of physical self-concept between T1 and T2. It is interesting that we found statistically significant effects for all three remaining predictor variables. Individual ability had a positive effect: When controlling for T1 physical self-concept, the better the students' ability test score, the higher their T2 physical self-concept. Moreover, even when T1 self-concept was statistically controlled, class-average ability significantly negatively predicted T2 physical self-concept; the effect size was  $\Delta = -0.36$ . In other words, class-average ability predicted T1 physical self-concept (see M1) and additionally predicted T2 physical self-concept when controlling for T1 physical self-concept. Finally, T1 physical activity positively predicted T2 physical self-concept as hypothesized; however, at  $B = 0.06$ , the regression coefficient was small.

The pattern of results was very similar when we additionally controlled for gender and BMI (see M12). Controlling for the other variables, gender and BMI did not statistically significantly predict T2 physical self-concept. Moreover, the addition of these two variables did not improve model fit relative to M11,  $\chi^2 = 3$ ,  $df = 2$ , *ns*.

In M13, we additionally included PE grades as a predictor variable. As illustrated in Figure 1c, inclusion of PE grades allows us to examine whether this variable functions as a mediator between T1 predictor variables and T2 physical self-concept. In line with our hypothesis, PE grade statistically significantly predicted T2 physical self-concept. Moreover, PE grade mediated some of the predictive power of the other variables. The direct predictive effect of T1 physical activity was no longer statistically significant when PE grades were included. In addition, the size of the predictive effects of individual and class-average ability decreased; however, controlling for the other predictor variables, both individual ( $B = 0.22$ ) and class-average ability ( $B = -0.21$ ,  $\Delta = -0.26$ ) predicted T2 physical self-concept. The inclusion of PE grades in M13 led to a statistically significant improvement in model fit compared to M12,  $\chi^2 = 109$ ,  $df = 1$ ,  $p < .001$ .

Taken together, frame of reference effects already observable at T1 (see M1 in Table 1) not only were stable, but their total size substantially increased between T1 and T2 (see M10). PE grades proved to predict T2 physical self-concept and mediated some of the frame of reference effects (see M13). Physical activity predicted T2 physical self-concept, but this effect was mediated by PE grades.

Our final set of analyses was performed with T2 physical activity as the outcome variable (see Table 3). In M14, T2 physical activity was regressed on individual and class-average ability. Both variables statistically significantly predicted T2 physical activity ( $B = 0.17$  for individual ability,  $\Delta = -0.25$  for class-

average ability). Hence, although physical ability was measured 15 months prior to T2 physical activity, membership of a class with high class-average physical ability was associated with less free-time physical activity at T2. At  $\Delta = -0.23$ , the effect was small. The model fit of M14 was higher,  $\chi^2 = 27$ ,  $df = 2$ ,  $p < .001$ , than that of an empty model with T2 physical activity as the outcome variable.

T1 physical activity and T1 physical self-concept were entered as additional predictor variables in M15. As expected, T1 physical activity had a high regression weight, indicating a considerable amount of stability in that behavior. In line with our hypothesis, T1 physical self-concept positively predicted T2 physical activity; however, the regression coefficient was rather small. Similarly, the effect of individual ability was statistically significant, but of a small size. No statistically significant effect was found for class-average physical ability when T1 physical activity was controlled.

In M16, gender and BMI were used as additional predictor variables; these two variables did not significantly predict T2 physical activity once T1 physical activity was controlled. Moreover, the regression coefficients of the other predictors were only slightly affected when these two predictors were included. The model fit of M16 was not a significant improvement on that of M15,  $\chi^2 = 4$ ,  $df = 2$ , *ns*.

Finally, in M17, we also included PE grade as a predictor variable. PE grade proved to statistically significantly predict T2 physical activity. In addition, the direct effects of individual physical ability and T1 physical self-concept were no longer statistically significant when the PE grade was included. Relative to M16, model fit was statistically significantly improved,  $\chi^2 = 8$ ,  $df = 1$ ,  $p < .01$ .

Taken together, the analyses documented frame of reference effects on T2 physical activity (see M14), but these effects were already present at T1 and did not increase between T1 and T2. Physical self-concept and PE grades statistically significantly predicted T2 physical activity; the regression coefficients were of small size, however.

## Discussion

Using a longitudinal framework and a large sample of preadolescents, the present study documented frame of reference effects on both physical self-concept and physical activity, attested to the role of performance feedback in the development of the physical self-concept and physical activity levels, and provided evidence for reciprocal effects between physical self-concept and physical activity levels. The study has major implications for both theory and practice.

### *Frame of Reference Effects and the Role of Performance Feedback*

Frame of reference effects as expressed in the BFLPE are an important and still much-debated phenomenon (e.g., Dai, 2004; Marsh & Hau, 2003; Plucker et al., 2004) with far-reaching effects on children's psychosocial development and behavior. The present study replicated the basic predictions of the BFLPE, but it also extended this research tradition. First, our study indicates that the BFLPE is not restricted to classical academic domains, such as mathematics or languages, but also applies to the domain of

physical ability. Moreover, our findings indicate that the BFLPE can be observed in students as young as about 9 to 10 years of age. Hence, frame of reference effects seem to emerge early in students' careers.

Second, the main focus in BFLPE research is typically on self-concept as the dependent variable (see Marsh, 1991, and Trautwein, Lüdtke, Marsh, et al., 2006, for exceptions). In our study, free-time physical activity level was examined in addition to physical self-concept. Clearly, physical activity level is a behavioral outcome with high educational relevance (see Biddle & Mutrie, 2001). Given that physical activity level is an out-of-school outcome that is likely to be affected by numerous out-of-school factors (e.g., parents, opportunity structures), it is all the more noteworthy that we found evidence for school-based frame of reference effects. Hence, our finding of a BFLPE on free-time engagement in sports significantly adds to the existing literature on frame of reference effects.

Third, our study is one of the first to systematically examine the impact of school grades on the BFLPE. It has been argued that the BFLPE might simply reflect norm-referenced grading practices in which classmates are used as the frame of reference, or at least that the BFLPE is strengthened by these practices (see Marsh, 1987; Trautwein, Lüdtke, Marsh, et al., 2006). The present study contributes to this debate in three ways. First, although students had not yet received any school grades for their performance at the first measurement point, the BFLPE was already apparent. Hence, the results demonstrate that the BFLPE is not simply the product of grading practices. Second, in line with our predictions, we found frame of reference effects in PE grades: Students with the same ability levels received lower grades when placed in a high-ability class. Third, the BFLPE was stronger for T2 physical self-concept than for T1 physical self-concept. Class-average ability negatively predicted T2 physical self-concept in a statistically significant way, even when T1 physical self-concept—including the effect of class-average ability on T1 physical self-concept—was controlled. In our view, it is likely that the introduction of PE grades—which were themselves subject to frame of reference effects—at the end of Grade 3 strengthened the natural frame of reference effects that were already in operation. The finding that the predictive effect of class-average physical ability on T2 physical self-concept was largely reduced when PE grades were entered in the regression model supports this hypothesis.

### *Reciprocal Effects Between Physical Self-Concept and Physical Activity*

Based on theoretical models and prior research (e.g., Eccles & Harold, 1991; Marsh, Chanal, & Sarrazin, 2006), we had expected to find evidence for a reciprocal relationship between physical self-concept and physical activity. Our analyses indeed revealed statistically significant reciprocal effects over time. However, with regression coefficients of  $B = 0.05$  and  $B = 0.06$ , the size of the predictive effects was somewhat smaller than anticipated and smaller than the correlation between the two variables ( $r = .24$  at T1) might suggest. What might be possible explanations for these rather small regression coefficients? First, our sample consists of preadolescents. It is quite possible that reciprocal effects between physical self-concept and physical activity are more pronounced in older students, who are able to regulate their behavior more au-

tonomously. Second, both physical self-concept and physical activity are likely to be multiply determined. For instance, whether or not students engage in organized free-time physical activities might depend to some extent on appropriate opportunities being available in the neighborhood and on their academic achievement. Likewise, although physical activity in clubs is likely to be associated with increased physical ability (see M9 in Table 2), frame of reference effects may mean that this relationship does not translate directly into higher physical self-concepts. Students in sports clubs may compare their own ability with their classmates, but also with other members of their clubs. The latter frame of reference may be more demanding.

### *Practical Implications*

Does social comparison decrease students' self-concept and constitute an obstacle to physical activity? As indicated by the negative effect of class-average achievement on self-concept and physical activity (the negative BFLPE), frame of reference effects are likely to be associated with negative developments in physical self-concept and physical activity in many students. This finding has important practical implications, to the extent that frame of reference effects may constitute an unassailable obstacle for programs aiming to promote physical activity. From a health perspective, the goal is to promote a sufficient level of physical activity among all students. Given the pervasive power of frame of reference effects, there will always be students with low physical self-concepts in mixed-ability PE classes, and the activity levels of these students are likely to be negatively affected by frame of reference effects.

How can educators and physical activity programs deal with frame of reference effects? One approach might be a change in student evaluation practices. In a study with more than 2,000 students from 112 classes, Lüdtke et al. (2005) showed that students' self-concepts are enhanced if their teachers apply an individualized frame of reference when evaluating student achievement. Teachers with an individualized teacher frame of reference emphasize improvement relative to prior achievement, effort, and learning. However, the findings also indicated that negative frame of reference effects were not suppressed. Future studies need to identify kinds of teacher feedback that may be able to enhance the physical self-concept of all students and reduce the negative effect of high-achieving reference groups.

### *Limitations and Future Research*

Certain limitations of our study should be kept in mind when interpreting the results. First and foremost, our study suffers from a limitation facing practically all real-world, nonexperimental research: the possibility of third-variable explanations. For instance, we predicted that high class-average ability would be associated with comparatively low physical self-concept when controlling for individual ability, and we found support for this hypothesis. According to our model, the statistically significant regression coefficient of class-average ability indicates that social comparison processes have taken place. However, it is equally possible that other unobserved variables caused or contributed to this association. Given the longitudinal study design and the control for potentially important third variables (gender, BMI), our study

might be relatively robust against third-variable explanations. Unfortunately, there is no perfect solution to this third-variable problem in nonexperimental, real-world studies in general or in the present study in particular. Although experimental studies seem to mitigate some of the problems of nonexperimental studies, our research design is not easily translatable to an experimental approach for ethical reasons.

Second, our physical activity variable only covered the organized setting of sports clubs. Other free-time sports activities were not considered. We believe this approach to be well-suited for our study for two reasons. One, preadolescents in Germany typically become involved in free-time sports activities in the context of such sports clubs. As a result of increasing urbanization, industrialization, and traffic density, people no longer get much exercise in daily life. It is now the institutional rather than the informal sector that offers opportunities to exercise. In fact, more than half of our participants were active members of sports clubs. Two, physical activity in sports clubs is typically characterized by higher frequency, regularity, intensity, and commitment than are other out-of-school physical activities. Hence, we believe that our physical activity variable captures the most important aspects of out-of-school physical activity. Nevertheless, future studies might also include measures of nonorganized physical activity.

Third, our study focuses on physical self-concept as a crucial motivational determinant of physical activity. As documented in the analyses, self-concept had a considerable impact on physical activity, both concurrently and prospectively. However, we acknowledge that other related constructs may also have predictive power. For instance, the expectancy-value framework developed by Eccles and colleagues (Eccles, 1983; Eccles & Harold, 1991; Wigfield & Eccles, 2002) complements the expectancy (self-concept) component by the value component, which comprises intrinsic value, attainment value, utility value, and cost. The studies by Eccles and colleagues (e.g., Eccles & Harold, 1991; Wigfield et al., 1997) indicate that this value component also contributes to explaining physical activity. Hence, our prediction of physical activity might have profited from including a value component.

Fourth, in a similar vein, we purposely focused on school-related factors as central determinants of physical self-concept and physical activity outside schools and did not address the important socializing role of parents or nonschool peers, the sports club setting, or the effects of various opportunity structures (e.g., geographical proximity to sport clubs, etc.). However, we were able to establish a remarkable association between school factors and children's out-of-school behavior. Given that our longitudinal study was the first to examine frame of reference effects on physical activity, we believe this decision to be justified, but we acknowledge that more comprehensive models would be preferable in future research.

Fifth, prior research (Marsh & Hau, 2003) has shown that the BFLPE is a worldwide phenomenon. We do not see much reason why the BFLPE should not also be observed in PE classes worldwide (see also Chanal et al., 2005). It is not clear, however, whether our findings regarding frame of reference effects on free-time physical activity generalize across different school systems. It would be interesting to conduct cross-cultural research on this issue in countries or communities with different organizational structures. We suspect that frame of reference effects are particu-

larly strong in school systems and communities where there is a close link between school-based physical education and free-time physical activity.

To conclude, the present research highlights the significance of physical self-concept for physical activity levels, documents that high-ability classmates have a negative effect on both physical self-concept and physical activity, and attests to the significant role of performance feedback in the development of the physical self-concept and physical activity levels. We believe that our findings have important theoretical and practical implications, and would like to see them prompt research on ways to counter the negative effects that high-ability classmates have on physical activity.

The main purpose of the *Journal of Educational Psychology* is to publish original, primary psychological research pertaining to education across all ages and educational levels. A secondary purpose of the *Journal* is the occasional publication of exceptionally important theoretical and review articles that are pertinent to educational psychology.

**Manuscript preparation.** Authors should prepare manuscripts according to the *Publication Manual of the American Psychological Association* (5th ed.). Manuscripts may be copyedited for bias-free language (see chap. 2 of the *Publication Manual*). Formatting instructions (all copy must be double-spaced) and instructions on the preparation of tables, figures, references, metrics, and abstracts appear in the *Manual*. For APA's Checklist for Manuscript Submission, see [www.apa.org/journals](http://www.apa.org/journals). **Abstract and keywords.** All manuscripts must include an abstract containing a maximum of 180 words typed on a separate page. After the abstract, please supply up to five keywords or brief phrases. **References.** References should be listed in alphabetical order. Each listed reference should be cited in text, and each text citation should be listed in the References. Basic formats are as follows:

- Haag, L., & Stern, E. (2003). In search of the benefits of learning Latin. *Journal of Educational Psychology*, 95, 174–178.
- Bollen, K. A. (1989). *Structural equations with latent variables*. New York: Wiley.
- Johnson, D. W., & Johnson, R. T. (1990). Cooperative learning and achievement. In S. Sharon (Ed.), *Cooperative learning: Theory and research* (pp. 173–202). New York: Praeger.

Adequate description of participants is critical to the science and practice of educational psychology; this allows readers to assess the results, determine generalizability of findings, and make comparisons in replications, extensions, literature reviews, or secondary data analyses. Authors should see guidelines for sample–subject description in the *Manual*. Appropriate indexes of effect size or strength of relationship should be incorporated in the results section of the manuscript (see pp. 5, 25–26 of the *Manual*). Information that allows the reader to assess not only the significance but also the magnitude of the observed effects or relationships clarifies the importance of the findings. **Figures.** Graphics files are welcome if supplied as Tiff, EPS, or PowerPoint. High-quality printouts or glossies are needed for *all* figures. The minimum line weight for line art is 0.5 point for optimal printing. When possible, please place symbol legends below the figure image instead of to the side. Original color figures can be printed in color at the editor's and publisher's discretion provided the author agrees to pay \$255 for one figure, \$425 for two figures, \$575 for three figures, \$675 for four figures, and \$55 for each additional figure.

**Publication policies.** APA policy prohibits an author from submitting the same manuscript for concurrent consideration by two or more publications. APA policy regarding posting articles on the Internet may be found at [www.apa.org/journals](http://www.apa.org/journals). In addition, it is a violation of APA Ethical Principles to publish "as original data, data that have been previously published" (Standard 8.13). As this is a primary journal that publishes original material only, APA policy prohibits publication of any manuscript or data that have already been published in whole or substantial part elsewhere. Authors have an obligation to consult journal editors concerning prior publication of any data on which their article depends. In addition, APA Ethical Principles specify that "after research results are published, psychologists do not withhold the data on which their conclusions are based from other competent professionals who seek to verify the substantive claims through reanalysis and who intend to use

such data only for that purpose, provided that the confidentiality of the participants can be protected and unless legal rights concerning proprietary data preclude their release" (Standard 8.14). Authors must have available their data throughout the editorial review process and for at least 5 years after the date of publication.

**Masked review policy.** The *Journal* has a masked review policy, which means that the identities of both authors and reviewers are masked. Every effort should be made by the authors to see that the manuscript itself contains no clues to their identities. Authors should never use first person (*I, my, we, our*) when referring to a study conducted by the author(s) or when doing so reveals the authors' identities, e.g., "in our previous work, Johnson et al., 1998 reported that . . ." Instead, references to the authors' work should be in third person, e.g., "Johnson et al. (1998) reported that . . ." The authors' institutional affiliations should also be masked in the manuscript. Authors submitting manuscripts are required to include in the cover letter the title of the manuscript along with all authors' names and institutional affiliations. However, the first page of the manuscript should omit the authors' names and affiliations, but should include the title of the manuscript and the date it is submitted. Responsibility for masking the manuscript rests with the authors; manuscripts will be returned to the author if not appropriately masked. If the manuscript is accepted, authors will be asked to make changes in wording so that the paper is no longer masked. Authors are required to state in writing that they have complied with APA ethical standards in the treatment of their sample, or to describe the details of treatment. A copy of the APA Ethical Principles may be obtained at [www.apa.org/ethics/](http://www.apa.org/ethics/) or by writing the APA Ethics Office, 750 First Street, NE, Washington, DC 20002-4242. APA requires authors to reveal any possible conflict of interest in the conduct and reporting of research (e.g., financial interests in a test procedure, funding by pharmaceutical companies for drug research). Authors of accepted manuscripts will be required to transfer copyright to APA.

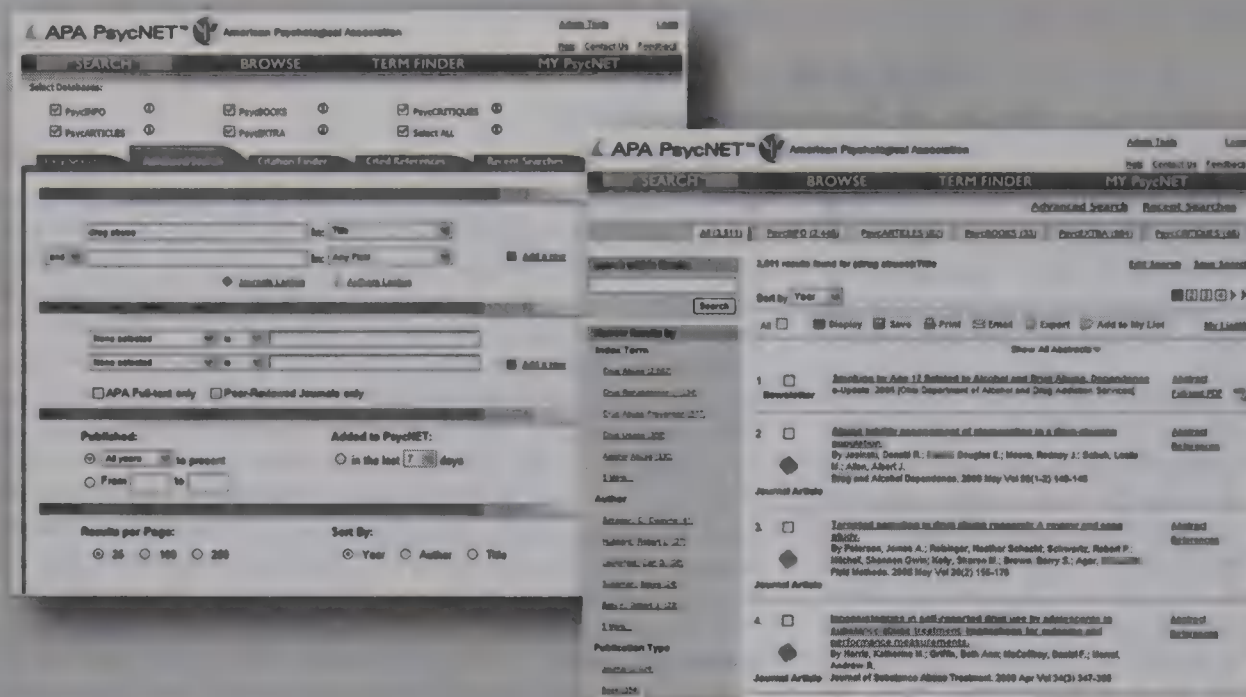

**Permissions.** Authors of accepted papers are required to obtain and provide to the editor on final acceptance all necessary permissions to reproduce in print and electronic form any copyrighted work, including, for example, test materials or portions thereof and photographs of people.

**Supplemental materials.** APA can now place supplementary materials online, which will be available via the published article in the PsycARTICLES database. To submit such materials, please see [www.apa.org/journals/authors/suppmaterial.html](http://www.apa.org/journals/authors/suppmaterial.html) for details. Authors of accepted papers will be asked to work with the editor and production staff to provide supplementary materials as appropriate.

**Submission.** Authors should submit their manuscripts electronically via the Manuscript Submission Portal at [www.apa.org/journals/edu](http://www.apa.org/journals/edu) (follow the link "Submit Manuscripts Electronically"). A checklist for manuscript submission, including guidelines for preparing the electronic file, can be found at [www.apa.org/journals/](http://www.apa.org/journals/). Correspondence regarding manuscripts should be sent to the Editor, Art Graessen, University of Memphis, Journal of Educational Psychology, 202 Psychology Building, Memphis, TN 38152-3230. In addition to addresses and phone numbers, authors should supply e-mail addresses, as most communications will be by e-mail. Fax numbers, if available, should also be provided for potential use by the editorial office and later by the production office. Authors should keep a copy of the manuscript to guard against loss. E-mail correspondence may be addressed to [jedgar@memphis.edu](mailto:jedgar@memphis.edu).

**Preparing files for production.** If your manuscript is accepted for publication, please follow the guidelines for file formats and naming provided at [www.apa.org/journals/authors/preparing\\_files.html](http://www.apa.org/journals/authors/preparing_files.html). If your manuscript was mask reviewed, please ensure that the final version for production includes a byline and full author note for typesetting.

## Maximize the Value of Your APA Membership

- Access over a century of psychological literature
- Discover millions of articles and book chapters in the social sciences
  - Browse the full text of APA journals from volume 1, issue 1
  - Download chapters from nearly 1,600 APA published books, including over 800 classic works

With **APA PsycNET®**, a world of behavioral sciences literature is at your fingertips. Choose from 3 database packages, each designed to meet specific professional needs:

- **APA PsycNET Silver** – access to the most current 3 years of journal literature

## APA Concise Dictionary of Psychology

A handy abridgment of the award-winning guide to the language of the field from the world's largest professional association of psychologists, with many updates and revised definitions

- 10,000 entries offering clear and authoritative definitions—including many revised and updated definitions from the parent dictionary (*APA Dictionary of Psychology*)
- Balanced coverage across core areas of psychology—including cognitive, personality, social, developmental, health, clinical, experimental, neuropsychology, research methodology, and many others
- Thousands of incisive cross-references to deepen the user's understanding of related topics
- A "Quick Guide to Use" that explains stylistic and formal features at a glance
- Appendixes listing major figures in the history of psychology and psychological therapies and approaches
- Use as a standalone reference or as a portable alternative to the *APA Dictionary of Psychology*

2009 | 592 pages | Hardcover | List: \$39.95 | APA Member/Affiliate: \$39.95

ISBN 978-1-4338-0391-8 | Item # 4311009

**RUSA Outstanding Reference Source**

**NYLA Best of Reference**

**Choice Outstanding Academic Title!**

## APA Dictionary of Psychology

With over 25,000 terms and definitions, the *Dictionary* encompasses all areas of research and application, and includes coverage of concepts, processes, and therapies across all the major subdisciplines of psychology. Ten years in the making and edited by a distinguished editorial board of nearly 100 psychological scholars, researchers and practitioners, the *APA Dictionary of Psychology* is destined to become the **most authoritative** reference of its kind.

*"This is an excellent reference work that should be ordered by every institutional library and every psychology department to make it accessible to students, faculty, researchers, and practitioners in all social science and health-related arenas."*

— **PsycCRITIQUES**

*"For the world's largest and most well known association of psychologists to produce a dictionary gives the work an 'out of the box' authority and prestige that few works share... Summing up: Essential."* — **Choice**

*"Ten years in the making, the American Psychological Association's (APA) new dictionary was well worth the wait."* — **Library Journal**, starred review

2006 | 1,024 pages | Hardcover | List: \$59.95 | APA Member/Affiliate: \$49.95

ISBN 978-1-59147-380-0 | Item # 4311009
